Somewhat similar variations in quality exist along the Colorado River from its headwaters in the Rocky Mountains to the Gulf of California, but the degree of change is smaller, due to the fact that the Colorado River is less developed relatively than the Rio Grande above Fort Quitman. In spite of this, however, the supply released from Lake Mead contains 30% more salt per acre-foot than water released at Elephant Butte; and, although the sodium percentage is not quite as high, the proportion of chlorides and sulfates is greater in the water discharged from Lake Mead than it is in the Rio Grande below Elephant Butte.

Valley Salt Balance

In addition to presenting a picture of what happens along the course of a river whose waters are used and re-used in the irrigation of land, the geochemical chart can be used to determine whether any salt is being accumulated in the lands irrigated.

Whenever the total amount of salt removed from an area exceeds the salt load of the incoming supply, it would appear that a favorable salt balance exists; however, this is not necessarily true. In many river valleys the ground waters are much more saline than the surface stream waters, as, for example, along the Rio Grande below El Paso. Water seeping from irrigation canals and percolating from fields tends to displace previous accumulations of ground water and to cause lateral movement toward any drains. Consequently, the drainage outflow is usually more saline than the contribution to the ground water.

Wherever this situation exists, the total quantity of salt in the effluent from a valley is likely to be greater than that in the influent to the same area, and this condition will hold until all the saline ground waters have been displaced. Therefore, it is necessary to do more than compute the difference between the salt load of the irrigation water and that of the drainage water.

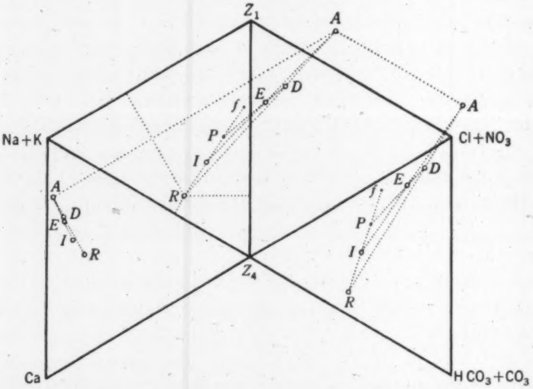
Table 4 shows the solution of such a problem for a 15,000-acre unit of the El Paso Valley. In the year 1934, which has been taken for illustration, 69,000 acre-ft of water, carrying 78,000 tons of dissolved solids of a type similar to that represented by point 7 in the graph insert of Table 3, were delivered into that area. The drainage effluent amounted to 27,000 acre-ft with a salt load of 140,000 tons. There was thus an apparent favorable salt balance amounting to 62,000 tons.

From a number of separate analyses made during that year, the total amount of each ion in the influent to that area, and in the effluent from it, were computed. These data are shown in Table 4. All other values given in the table are computed. The apparent gain (that is, the amount by which the salts in the effluent exceed the salts in the influent) is merely the difference between these quantities. The net gain in positive ions amounted to 244 T_e of calcium, 29 T_e of magnesium, and 806 T_e of sodium, making a total of 1,079 T_e removed from the area with the drainage water in excess of the amount brought in with the irrigation water.

The simple difference between the amount of chloride brought in and the amount removed shows an apparent gain of 1,261 T_e, which is 182 T_e greater than the net amount of cations removed. This excess is offset by the apparent accumulation of 122 T_e of HCO_3 and 60 T_e of SO_4

In any quantity of water there must be the same equivalent weight of positive ions as there is of negative ions. It follows, therefore, that, with the 182 T_e of chlorides in excess of the total of the positive ions, there were 182 T_e of cations in the effluent that were not brought into the area during the same year. Furthermore, with these 182 T_e of cations displaced from some source within the area, there must have been another 182 T_e of anions. In these anomalies lies the solution of the problem of how much of the influent salt was left in this part of El Paso Valley and how much of the salt already accumulated was removed from it.

TABLE 4.—VALLEY SALT BALANCE; KNOWN DATA AND COMPUTED VALUES[a]



Line	Unit	Cations			Σ	Anions		
		Ca	Mg	Na		HCO_3	SO_4	Cl
INFLUENT SALT, *I*								
1	T_e	465	166	664	1,295	332	576	387
2	%	35.9	12.8	51.3	100.0	25.6	44.5	29.9
EFFLUENT SALT, *E*								
3	T_e	709	195	1,470	2,374	210	516	1,648
4	%	29.9	8.2	61.9	100.0	8.8	21.8	69.4
APPARENT GAIN, *A*								
5	T_e	244	29	806	1,079	−122	−60	1,261
6	%	22.6	2.7	74.7	100.0	−11.3	−5.6	116.9
DISPLACED SALT, *D*								
7	T_e	458	130	1,036	1,624	92	216	1,316
8	%	28.2	8.0	63.8	100.0	5.7	13.3	81.0
RESIDUAL SALT, *R*								
9	T_e	214	101	230	545	214	276	55
10	%	39.3	18.5	42.2	100.0	39.3	50.7	10.0

[a] All values for displaced and residual salts are computed.

The necessity of considering more than just the difference between the amount of salt brought in and that removed becomes more apparent when the data are plotted on the geochemical chart. Point I, Table 4, represents the influent, point E the effluent, and point A the apparent gain. Point A, however, falls outside of the anion triangle, and likewise outside of the geochemical diamond. This could not be the case if the excess amount of salt in the effluent resulted only from the removal of previous accumulations, because no water can contain less than zero of any ion. The apparent gain must, in itself, be the difference between the total salts displaced from the area and the amount of influent salts left behind in the soil or in the ground water.

The approximate magnitude and character of the displaced salts and the residual salts can be computed from the following relationships:

$$I = R + P \qquad (2a)$$

$$E = P + D \qquad (2b)$$

$$E - I = A \text{ or } E = I + A \qquad (2c)$$

$$P + D - R - P = A \qquad (2d)$$

and

$$D - R = A \text{ or } D = R + A \qquad (2e)$$

in which: I is the amount of influent salts; E is the amount of effluent salts; P is the amount of the influent salts that passes through the area within the period of time under consideration; R is the amount of salts left behind in the soil or in the ground water; and D is the amount of salts displaced from the soil or from the ground water.

From Eqs. 2, E thus can be considered a mixture of I and A; likewise, D can be treated as a mixture of R and A. Consequently, the points I, E, and A must lie on a straight line, and the points R, D, and A must also lie on a straight line. Furthermore, the positions of the points along these lines must be such that there will be equilibrium of forces when the equivalent total weight of each is treated as a force normal to the paper.

If moments are taken about the base opposite the vertex corresponding to any ion or geochemical group, the percentage of that ion or group can be used as the lever arm of the force. In Eqs. 3 such percentages are designated by the letter C with appropriate subscripts:

$$C_i \times I + C_a \times A = C_e \times E \qquad (3a)$$

and

$$C_r \times R + C_a \times A = C_d \times D \qquad (3b)$$

There are four unknowns in Eqs. 3—namely, C_r, R, C_d, and D. Eq. 3(b) and the equation of mass (that is, Eq. 2(e)) are the only simultaneous equations available for determining these unknowns. Consequently, an infinite number of solutions of the problem are possible. The position of points R and D on the geochemical chart are circumscribed by other factors, however, so that the magnitude of these values can vary only within limits.

The smallest possible amount of residual salt was 182 T_e; if this were the correct value, point D would be at the chloride vertex of the anion triangle, indicating the displacement of no other ion from the soil or from the ground water; it also would require that the salts left behind include no chlorides. Neither presumption is warranted. There was probably no percolate from some irrigated fields, so that a part of the residual was substantially of the same character as the influent salt. All of the canal seepage could not have reached the effluent drains within the period of time under consideration; this residual was also of the same character as the influent. In other parts of the area where there was free drainage, probably no chlorides were left behind. It is reasonable, therefore, to assume that the residual salts contained substantially 10% of chlorides. Under this assumption, point *R* must lie on a line parallel to the base opposite the chloride vertex of the anion triangle and 10% of the distance from that base toward the chloride vertex.

The residual being one element of a mixture which is represented by the influent, the other element of the mixture (that is, point *P*) must lie on the prolongation of the line *RI*. Point *P* is in itself a mixture of canal water and field percolate. The canal water is the same as the influent; therefore, the position representing the field percolate must lie on the prolongation of the line *IP* at some such point as *f*, shown in Table 4. Any field percolate will be low in carbonates but presumably will contain some carbonates.

Point *D*, Table 4, is indicative of the character of the salts displaced from the soil and the ground water. These are naturally high in chlorides, and it is reasonable to assume ordinarily that only about 30% of the salts are sulfates and carbonates. In the solution of the particular problem used for illustration, certain analyses of well waters were available which indicated that the displaced salts contained more than 80% chlorides.

The location of points *R* and *D* in Table 4 were selected with consideration to these factors; the magnitude of the quantities were computed from Eqs. 2 and 3. The resulting values are shown in Table 4. It will be noted that the apparent gain of 1,079 T_e of salts during 1934 was probably brought about by the displacement of 1,624 T_e of salts from the soil and the ground water and the accumulation of 545 T_e of the salts in the irrigation supply. Other reasonable solutions of this problem are possible, but the magnitude of the residual cannot be changed to any large extent without making extreme assumptions. There is ample reason to assume that the true residual was between 450 T_e and 650 T_e and that the large net gain in chlorides resulted from the displacement of saline ground water.

The character of salts left behind as a result of irrigation in this part of the El Paso Valley can be computed from the chart. The perpendiculars to point *R* on the geochemical diamond are proportional to the magnitude of the various groups. These magnitudes are as follows:

Group	Tons-equivalent
Z_1	54.5
Z_2	175.5
Z_4	315.0

Substantially all of Group Z_1 was sodium chloride, so that the total amount of this group left behind can be computed by multiplying 54.5 T_e by the sum of the combining weights of sodium and chloride (namely, 23.0 + 35.5), giving roughly 3,200 tons. In Group Z_2 there was evidently no sodium bicarbonate because there was ample calcium present to combine with the carbonates. Accordingly, it was found that 12,500 tons of sodium sulfate were left in the area as a result of irrigation. Computation of the amount of the different salts included in Group Z_4 involves the assumption that certain combinations will be formed. These hypothetical combinations are quite uncertain, but to complete the picture it can be estimated that 6,100 tons of magnesium sulfate and 10,700 tons of calcium carbonate were included in the residual.

Approximately 32,500 tons of various salts out of the 78,000 tons brought in by the irrigation water in 1934 were thus left behind as a result of the irrigation of less than 15,000 acres. From this it follows that two thirds of the salt load of the drainage water was derived from the saline waters underlying the area, and that the salt balance within the root zone was probably adverse.

In addition to this accumulation of mineral salts in the soils of the area, it appears that there was some accumulation of sodium as a result of base exchange. The displaced salts contained 17.2% of the Z_3 Group, which is made up primarily of the chlorides of calcium and magnesium. The amount of magnesium displaced was only 8% of the cations so that about one half of the Z_3 Group of displaced salts was calcium chloride. It is unlikely that calcium chloride would be present unless there had been base exchange, because of the character of the influent water. The probability that calcium was displaced from the soil colloids by sodium is also indicated by the proximity of point *D* on the cation triangle to point *E*.

The assumption that a favorable salt balance is established whenever the total of the effluent salts exceeds the total of the influent salts may thus be erroneous. It is important to ascertain in fact whether a favorable salt balance is being maintained within the root zone of the irrigated fields, because any accumulation of salt in the upper soil horizons, no matter how slow, must eventually render irrigation agriculture unprofitable.

Necessity for Further Study

This paper has been presented for two purposes: First, to offer to the engineering profession a convenient tool for the interpretation of chemical analyses of stream and ground waters; and second, to stimulate irrigation engineers to consider quality of water to be as important as quantity.

The data presented were selected primarily in illustration of the geochemical chart developed by the writer and of the methods used in its application to irrigation problems. Much more study of these problems by irrigation engineers and agriculturalists is needed, to the end that successful irrigation agriculture may be permanent rather than temporary.

DISCUSSION

C. S. SCOFIELD,[3] ESQ.—Mr. Hill, in this paper, undertakes to extend and improve a system of water classification proposed by Chase Palmer[2] before 1911. The writer would be less than frank if he did not state at once that there exists among hydrologists a difference of opinion as to whether Mr. Palmer's classification should be retained in use even if revised. One school holds that it would be better to forget it. The writer does not feel called upon at this time to support either side of that question.

It seems both obvious and uncontrovertable that the methods currently in use for reporting on the quality of water are unsatisfactory. There are almost as many methods of reporting water analyses as there are water analysis laboratories. Under present conditions it requires the services of an expert hydrologist and a computing machine to reduce the findings of two or more laboratories to a common basis so that comparisons between them are possible.

It was not until June 25, 1941, that definite steps were taken to remedy this regrettable condition of affairs. On that date, Committee D-19 of the American Society for Testing Materials adopted the report of its subcommittee on the analyses of industrial waters. The fundamental basis adopted by Mr. Hill is in harmony with the method recommended by that Committee.

However, it is evident that Mr. Hill's objectives lie beyond the relatively simple one of obtaining uniformity of method in reporting water analyses. He has two major objectives: (1) To illustrate by means of diagrams the salient characteristics of two or more waters; and (2) to use these diagrams as an aid in solving certain perplexing hydrological problems along streams, such as finding the sources of salt contamination or finding the places in which salt is deposited.

The writer approves and supports his efforts in the direction of his first objective. These are illustrated in Fig. 1 and Tables 1 and 3. These diagrams show effectively the important differences between the waters of two streams in the Salt River Valley and the progressive changes in concentration and in composition that occur in the Rio Grande between Del Norte and Fort Quitman. No doubt, the essential facts in these two situations would be apparent to an expert hydrologist who examined the tabulated analytical data, but these facts become apparent to a much larger number of persons when they are illustrated as they are in these diagrams.

In respect to the second objective—that of solving problems of the source or the destination of water-borne salinity—the writer finds himself less positive, and in fact somewhat perplexed. The problems involved are of great importance, and any serious attempt to solve them is to be commended; but the writer must admit his own inability to evaluate this method of attack.

It may be appropriate to discuss certain phases of the subject of this paper that Mr. Hill has not emphasized—namely, the nature of the effects of salt constituents on the soil and on plants. One important constituent that is not mentioned in the paper is boron. This element is important because it is one of a small number of elements that are absolutely essential for plant growth. It is important also because in some situations it occurs in irrigation waters and ultimately in the soil solution in such high concentrations as to injure crop plants or even to prevent growth. In other situations (not only in irrigated lands but elsewhere), the quantity of available boron is so small that it is necessary to supply it artificially in order to obtain normal crop growth. Because of these facts, any general discussion of the salts of irrigation water should include boron, and any classification of such waters should take it into account.

---

[3] Principal Agriculturist, U. S. Bureau of Plant Industry, Washington, D. C.

The importance of sodium as a constituent of irrigation water is fully recognized in Mr. Hill's classification. The writer will merely point out some of the reasons for its importance. So far as is known, sodium is not one of the elements essential to plant growth. However, it is almost always present in irrigation water and in the soil solution; and whenever salinity concentrations are high, sodium is almost always the dominant basic or cation constituent. Plants absorb very little sodium from the soil solution even when its concentration in that solution is high. It is not known to produce injurious effects within the plant, probably because most plants do not absorb it in large quantities. Its presence in high concentrations in the soil solution is directly injurious to plants chiefly because of osmotic effects of its salts, which retard the absorption of water by plant roots.

Sodium is chiefly injurious because of its effect on the physical condition of the soil. The soil contains minerals and organic compounds that participate in reactions of base exchange. Reactions of this type are widely known and extensively utilized in many industries, particularly in zeolitic water softeners. In the soil, high concentrations of sodium in the solution tend to replace calcium and magnesium from the mineral and organic complexes with the result that the physical properties of the soil are impaired. The soil becomes gelatinous and relatively impermeable to the movement of water.

The rate and extent of the replacement of calcium and magnesium by sodium depend upon the relative concentrations of these constituents in the soil solution. Thus the injurious effects of sodium occur only when its concentration is higher than that of the calcium and magnesium. This is the reason for emphasizing the relative concentration of sodium rather than its absolute concentration. By way of summary it may be stated that, so far as is known, sodium serves no useful purpose in irrigation water or in the soil solution. It becomes definitely harmful to the soil and thus indirectly to plants when its concentration becomes much higher than the sum of the calcium and magnesium.

It seems appropriate now to discuss briefly three other basic or cation constituents of irrigation water and the soil solution. These are calcium, magnesium, and potassium. They are all elements essential to plant growth. Of the three, potassium is the one most largely absorbed by plants. In fact, plants absorb it so avidly that it is seldom found in high concentrations even in very saline soil solutions or in drainage waters. Potassium deficiency is common, but potassium toxicity is very rare. Calcium and magnesium are often grouped together. They have some characteristics in common; for example, together they make up the hardness that is troublesome in waters intended for domestic and industrial uses. They differ in one important particular—namely, calcium combines with the anion, sulfate, to form a salt of low solubility (0.2%), whereas the corresponding salt of magnesium is one of the highest in solubility. This means that, whereas calcium seldom occurs in toxic concentrations even in very salty solutions, magnesium may do so, and may thus contribute to the high osmotic values in the soil solution that retard the absorption of water by plants.

The writer hesitates to take the space to discuss in detail the salt constituents of the anion group—namely, the carbonate-bicarbonate complex, the sulfate, chloride, and nitrate. There is much to be found in literature about the harmfulness of the carbonate-bicarbonate constituent, the so-called "black alkali." The injurious potentialities of this constituent are overrated. Most of the trouble allegedly due to black alkali is caused by sodium; and sodium is no less harmful when it occurs with sulfate, chloride, or nitrate than when it occurs with carbonate or bicarbonate. Furthermore, both carbonate and bicarbonate form salts of low solubility with calcium and may thus be made innocuous at small expense.

Of the other three anions, sulfate and nitrate at least are both essential to plant growth. In this respect there is some doubt about chloride. Nitrate is so largely absorbed by plants that it seldom occurs naturally in toxic concentrations. In artificial culture solutions it has been shown to be slightly more toxic than equivalent concentrations of chloride. Both of these constituents are more toxic than equivalent concentrations of sulfate.

In these remarks the writer has discussed four cation constituents and five anion constituents that occur in the salts of irrigation water. He has emphasized the constituents, rather than the salts they may form, because in water solutions, and in respect to their effects either on the soil or on the plants, they operate as constituents rather than as salts. Some of them operate independently, whereas the effects of others are modified by their associates. The method of reporting and illustrating the characteristics of irrigation water as proposed by Mr. Hill is unquestionably of value in the direction of simplifying this complex problem. There can be no doubt that its complexity has been one of the reasons why its economic implications have not been more widely understood. However, one must not overlook the dangers of oversimplification. With this in mind the writer wishes to indorse particularly Mr. Hill's concluding sentence in which he states that much more study of these problems by irrigation engineers and agriculturists is needed.

HERMAN STABLER,[4] M. AM. SOC. C. E.—Too few engineers are sufficiently interested in quality of water to delve into the mysteries of water chemistry, and too few chemists are sufficiently interested in the engineering applications of the water analyses they make to consider the impact of quality of water on industrial and agricultural development. The author has done a service to the engineering profession by invading that twilight zone between engineering and chemistry and bringing back and presenting to engineers a classification of waters in terms of their chemical constitution and an ingenious method of expressing chemical quality and classification in graphical form.

---

[4] Chf , Conservation Branch, U S. Geological Survey, Interior Dept., Washington, D. C.

In general, the author follows the Palmer method of considering waters as a balanced system of chemical values. Palmer[5] advocated the statement of a water analysis in four parts:

(1) The properties of the solution in percentage proportions (in which he grouped radicals to indicate "properties," of which there would be but three to any water; properties so determined fixed the "class" of the water);

(2) The percentage reacting values of groups of radicals accompanied by a statement of concentration values;

(3) The "character formula"—the percentage reacting values of the individual radicals—together with a statement of concentration values; and

(4) The base analyses.

Palmer's designation of the "class" of a water, or of the "properties" that determine the class, provides a generalized chemical picture of the water that is scientifically correct and convenient for some purposes but is inadequate for industrial or agricultural evaluation because it recognizes no difference in effect of the individual radicals grouped. The author departs slightly from the Palmer grouping of radicals and states (see heading "Geochemical Classifications"): "For the interpretation of analyses of water used in agriculture it was felt desirable to group the sulfates with the carbonates rather than with the chlorides and nitrates." He thus violates the chemical logic of the Palmer grouping without seeming to gain anything in application to irrigation engineering. The writer wonders why.

Palmer's character formula gives a detailed chemical picture of a water portraying the particular place it occupies in an infinite series of "classes." Many individuals of this infinite series are grouped in the few major classes based on "properties." Together with concentration value, the character formula can be applied to the solution of many industrial and irrigation problems. The author follows the principle of Palmer's character formula with the exception that his percentage reacting values (or equivalents per million) add up to 200 instead of 100. Here again the writer sees no gain. Calculating the percentages of "anions" and "cations" separately is desirable, but it is as easy to make the sum of each 50, thus preserving the concept of 100% for the whole, as to double the values as the author has done.

The author's diagrammatic representation of a water by a single point, or by designation (for example, as a Type II or Type *b*II*c* water), carries with it a degree of significance but leaves out of the picture rather important detail. Designation of Type *b*II*c* for the Verde River water, for example, means (following the author's definitions) that this is "a water in which no one of the positive ions exceeds 50% of the total" but "in which more than 50% of the anions are bicarbonates or carbonates," in which most of the salts fall in a group of Ca, Mg, SO_4, $H\ CO_3$, and CO_3 ions, some in a group of Na, K, SO_4, $H\ CO_3$, and CO_3 ions, and none in a group of Ca, Mg, Cl, and NO_3 ions (see heading "Types of Water"). All of this and more would be disclosed in Palmer's character formula which, for the same water, would be 21.6 Ca, 17.2 Mg, 11.2 Na, 36.1 $H\ CO_3$, 9.2 SO_4, 4.7 Cl, simulating the formula for any other mineral.

---

[5] "The Geochemical Interpretation of Water Analyses," by Chase Palmer, *Bulletin No. 479*, U. S. Geological Survey, 1911, p. 14.

Diagrams showing characteristics of waters and adapted to comparison of several analyses have been developed by a number of people. The writer has been accustomed to use the form shown in Fig. 2, in which comparison is made of the nine waters in Table 3. This diagram shows, in parallel columns (instead of in two separate triangles as shown by the author), the factors entering into the Palmer character formula, and, in width of column (instead of area of circles as shown by the author), the concentration factor which, together with the character formula, makes up the complete detailed picture of a water analysis. The writer finds it easier to diagnose the character of a water and to compare the several characteristics of a group of waters from Fig. 2 than from the author's "geochemical chart" (Fig. 1), but recognizes that this may be largely if not wholly due to habit and his greater familiarity with the one than with the other. Both schemes accomplish essentially the same purpose, and choice between them resolves itself largely into a matter of personal preference. Fig. 2 shows at a glance the variations from upper to lower reaches of the river, which are:

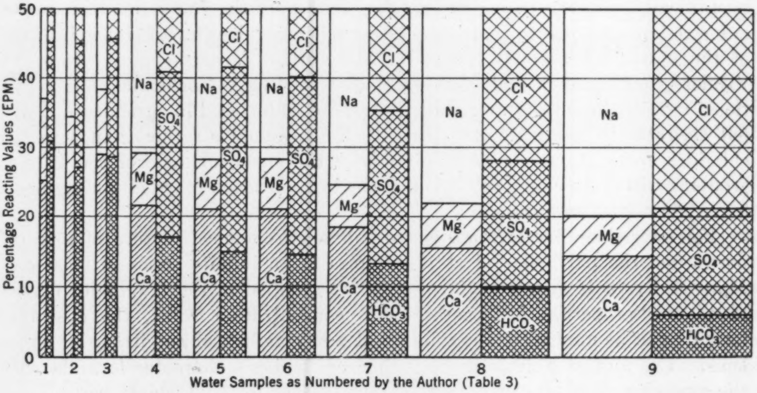


FIG. 2.—GRAPHICAL REPRESENTATION OF "CHARACTER" FORMULA (PALMER) AND CONCENTRATION VALUE FOR WATERS OF THE RIO GRANDE (WIDTH OF COLUMNS PROPORTIONAL TO CONCENTRATION, COL. NO. 1 BEING DOUBLE SCALE)

(1) Progressive increase in concentration until at Fort Quitman concentration is nearly thirty times as great as at Del Norte;

(2) Progressive decrease in the percentage of Ca from Del Norte to Fort Quitman interrupted by a maximum at Otowi;

(3) Progressive decrease in the percentage of Mg;

(4) Progressive increase in the percentage of Na + K interrupted by a minimum at Otowi;

(5) Progressive decrease in the percentage of CO_3 + H CO_3 interrupted by a sub-maximum at Otowi;

(6) Progressive increase in the percentage of SO_4 from Del Norte to Elephant Butte (except for slight decrease at Otowi), followed by progressive decrease downstream; and

(7) Progressive decrease of the percentage of Cl from Del Norte to Otowi, followed by a rather sudden increase to San Marcial and Elephant Butte and then by progressive increase downstream.

These variations can likewise be visualized from the author's anion and cation triangles in the geochemical chart in Table 3 or from a table of radicals by reacting values and concentration values (Palmer's third item in the statement of an analysis). The changes in "class" shown in the author's diamond in the geochemical chart are progressive increase (except for Otowi) in percentage hardness, progressive decrease (except for Otowi) in percentage saltness, and general progressive decrease in percentage alkali to Elephant Butte, followed by progressive increase downstream. Do these add anything of importance in evaluating an irrigation water? The writer thinks not. Had the author adhered to the Palmer grouping for properties there would be: A general progressive decrease of secondary alkalinity (beneficial or inert for irrigation); progressive increase of secondary salinity (beneficial for irrigation) to Leasburg, followed by decrease at El Paso and increase thereafter; and progressive increase (except at Otowi) in primary salinity (harmful for irrigation). The irrigation picture, however, would not be very well defined. In evaluating waters for industrial use or for irrigation the writer prefers to use formulas adapted especially to the particular problem in hand rather than to trust to any general geochemical classification.

The author does not attempt to describe the effect of different kinds of water on soil and on plant growth but expresses the hope that some discusser will do so. The writer has not been so cautious. In 1910[6] he prepared an article on "The Relative Value of Irrigating Waters" that was republished[7] one year later with modifications as part of a more comprehensive treatment of industrial interpretation of water analyses.

Irrigation waters were discussed, formulas were given for computing the "alkali coefficient" (an indicator of value for irrigation purposes), and a classification of irrigation waters was set forth. The treatment there accorded the subject of irrigation waters, though far from adequate, has proved very useful in certain phases of water evaluation by the writer. The data then available were meager, and more accurate formulas doubtless could be devised on the basis of the wealth of information and experience now available. This classification of irrigation waters includes consideration of only the common constituents reported in water analyses. Any adequate treatment of the subject would have to take into consideration such substances as boron which, although present in irrigation waters in small amounts, may exert a potent influence on plant life.

---

[6] *Engineering News*, Vol. 64, No. 2, July 14, 1910, p. 57.

[7] *Water Supply Paper No. 274*, U. S. Geological Survey, Washington, D. C., 1911 (including on p. 165 a chapter on "The Industrial Application of Water Analyses")

For what it is worth the writer presents in Fig. 3, by the method outlined in *Water Supply Paper No. 274*, on semilogarithmic scale, the alkali coefficient, class, and class description of the nine waters of the Rio Grande whose analyses are supplied by the author. The waters at and above Otowi are shown to be of very high class for irrigation purposes; those at San Marcial, Elephant Butte, and Leasburg are shown as "good" but little better than "fair"; the water at El Paso is shown as "fair"; and those below El Paso as "poor." How nearly do these classes and the relative magnitude of the alkali coefficients on which they are based reflect the experience of the water users along the Rio Grande?

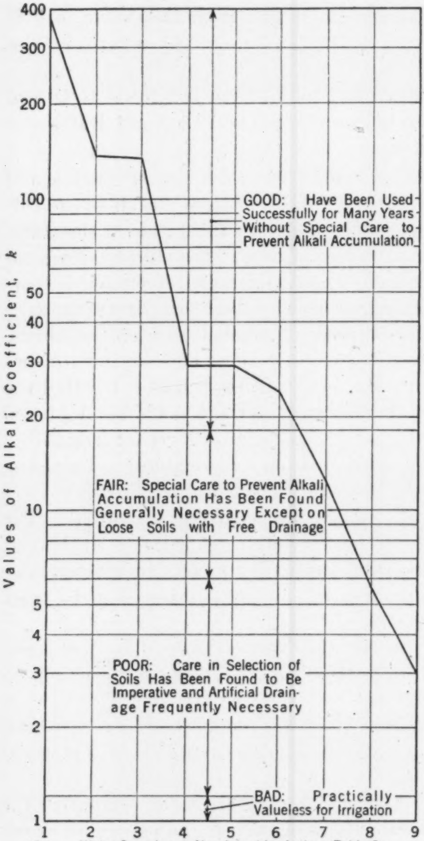

FIG. 3.—CLASSIFICATION AND RELATIVE VALUE FOR IRRIGATION OF WATERS OF THE RIO GRANDE

In 1935 Carl S. Scofield[8] discussed the many "variables that must be considered in determining the relationship between the quality of irrigation water on the one side and of a profitable and enduring system of irrigation agriculture on the other." With a warning that the class limits or standards given are intended for use in a particular area and should not be taken as applicable everywhere, he presents the values in Table 5 as an example of the permissible limits, adopted for a definite region, of classes of irrigation water with respect to certain of its characteristics.

Applying the standards of Table 5 to the nine Rio Grande waters whose analyses are submitted by the author (a procedure that Scofield would probably regard as incautious), the series of classifications in Table 6 is derived and compared with the writer's alkali coefficient and classification.

By either system the first two waters stand out as of high class; the third is equally good by the writer's classification but slightly poorer by Scofield's; the fourth rates about the same under the two classifications; the fifth and sixth, almost identical with the fourth according to the writer's classification, are slightly poorer by Scofield's; and the two classifications give about the same result on the eighth and ninth waters.

5	Unsuitable	>300	>2,100	>80	>1.25	>2.50	>3.75	>20	>20

[a] The concentration of dissolved salts in water may be measured by either of two methods—that of electrical conductance and that of evaporating the water and weighing the residue. [b] This percentage represents the proportion of sodium to the total cations and is computed from the data of analysis, reported as milligram equivalents, by dividing the sum of the values for sodium and potassium by the sum of the values for all the cations.

In general, the two classifications should give similar results except with primary alkaline waters (a class not represented in the nine waters of the Rio Grande) for which the writer's classification would be substantially more severe. This is explained by a more lenient evaluation of carbonates by Scofield in the light of the experience of later years. Computation of the writer's alkali coefficients was developed under the older viewpoint and presupposes Na_2CO_3 twice as undesirable as Na Cl and ten times as undesirable as Na_2SO_4.

TABLE 6.—COMPARISON OF CLASSIFICATIONS

Water No.	SCOFIELD CLASSIFICATION				"Alkali coefficient"	Class
	Concentration	% of Na	Chlorides	Sulfates		
1	Excellent	Good	Excellent	Excellent	356	Good

M. R. LEWIS,[9] M. AM. SOC. C. E.—The importance, not only of the total quantity of dissolved salts, but also of the character of the salts is shown well by Mr. Hill. There is need for more general knowledge and consideration of both factors in irrigation practice.

---

[9] Senior Agri. Engr., SCS, U. S. Dept. of Agriculture, and Oregon State College, Corvallis, Ore.

In the Pacific Northwest there appears to be a close correlation between the pH-value of soils and soil solutions with the productivity and ease of reclamation of alkali lands. Herein and in common usage the term "alkali" includes both saline (white alkali) and alkaline (black alkali) soils. For this reason the carbonate and bicarbonate content appears to be of particular importance in agricultural practice. To the extent that this is true, it would be better to retain Mr. Palmer's method[2] of grouping the SO_4 ion with the Cl, rather than with the $H\ CO_3$ and CO_3 ions. Apparently, the alternative grouping is necessary in the development of the author's geochemical chart.

Mr. Hill's conclusion that some salts from the irrigation supply are retained in the valley and that a large part of the salts carried out with the drainage water come from the original ground water, and also his determination of the approximate character of both, seem well founded. His opinion, that the residual salts are held in the soil and not in the ground water and that the general result of irrigation in the area is adverse, seems open to argument. C. S. Scofield[10] has shown that ground water held near the surface of irrigated soils does not move rapidly to the drainage channels. Is it not probable that a large part of the "residual" salts are held in the ground water below irrigated fields rather than in the soil of the root zone? Since these residual salts are of less harmful quality than either the influent salts or the displaced salts, it would appear that the net result of the changes may well be beneficial rather than harmful.

The evidence of base exchange activity in the soil is another matter. Truly more study is needed.

Louis J. Alexander,[11] Assoc. M. Am. Soc. C. E.—Mr. Hill is to be commended for his paper. He has offered a solution to one of the most perplexing of all geochemical problems; this is, the accurate determination of the source or sources of the resultant mixture of water. Heretofore such solutions were dependent upon the method of trial and error.

Another, and perhaps more important, development in the paper is the method of forecasting what may happen to the soil complex because of the use of water of varying character. If this forecast is applied to one of the local (Southern California) sources, solution of a very controversial problem might be found.

The paper uses the words "character," "type," and "quality" synonymously. Misuse of these terms is common. The writer, however, believes that they should not be so used. "Character" is the "relationship of the ions contained in the solution," one to another and to the whole, and "type" is applicable as a subclassification under "character," whereas "quality" is the "relationship of the concentration of dissolved minerals of other impurities."

The writer has been studying the character, type, and quality of well waters pumped from the Los Angeles Coastal Plain for a number of years.[12]

---

[10] "The Movement of Water in Irrigated Soils," by C. S. Scofield, *Journal of Agricultural Research*, Vol. 27, 1924, pp. 617–694.

[11] Designing Engr., Southern California Water Co., Los Angeles, Calif.

[12] "Character, Quality and Treatment of Well Water Supplies of the Los Angeles Coastal Plain," by Louis J. Alexander, presented at the meeting of the Sanitary Engineering Division of the Society, July 24, 1941, San Diego, Calif.

In Southern California consideration of domestic waters must include agricultural and industrial applications. The writer proposes four character types: Two types of carbonate water, a sulfate type, and a chloride type. These four "characters" are defined as follows:

1. Carbonate Waters.—The weak acids exceed the strong acids; alkalies exceed strong acids (no non-carbonate hardness): (CO_3 + H CO_3) exceed (Cl + SO_4); (Na + K) exceed (Cl + SO_4).

2. Carbonate Waters.—The weak acids exceed the strong acids; the earths exceed the weak acids (some non-carbonate hardness): (CO_3 + H CO_3) exceed (Cl + SO_4); and (Ca + Mg) exceed (CO_3 + H CO_3).

3. Sulfate Waters.—Strong acids exceed the weak acids and the sulfates exceed chlorides; the earths exceed the weak acids: (Cl + SO_4) exceed (CO_3 + H CO_3); (SO_4) exceeds (Cl); and (Ca + Mg) exceed (CO_3 + H CO_3).

4. Chloride Waters.—Strong acids exceed the weak acids and chloride exceeds sulfate; the earths exceed the weak acids: (Cl + SO_4) exceed (CO_3 + H CO_3); (Cl) exceeds (SO_4); and (Ca + Mg) exceed (CO_3 + H CO_3).

This is a much broader classification than the one proposed by Mr. Hill, but it is believed, for ordinary uses, more satisfactory. This classification is based upon the relative concentrations of the acid groupings rather than upon assumed combinations of various ions and radicals. The reason for this selection is that, in the consideration of the treatment of water, these relationships become important. This is especially true of the waters in sulfate and chloride groups.

A method of study and classification developed by O. A. Stone, M. Am. Soc. C. E., similar to that by Mr. Hill has been used by the writer for some years in the study of localized problems of some complication, but both methods have been found to be somewhat laborious in the study of broad classifications for general work.

Mr. Hill suggests the need for further study. The writer believes that such study should also be enlarged to include waters used for domestic and industrial as well as irrigational uses.

W. D. COLLINS,[13] ESQ. (by letter).—The new and original method of treating the subject of salts in irrigation waters that is so clearly advanced by the author will undoubtedly prove a useful tool in the hands of those who like to deal with physical and chemical phenomena by means of graphs and equations.

Graphic Representation of Analyses.—Persons not in the habit of using triangular coordinates may be discouraged by the apparent complication of the system proposed by Mr. Hill. The system of graphic representation of water analyses used mainly by the U. S. Geological Survey[14] is based on analyses in terms of equivalents per million, as is the author's system. Figs. 4 to 9 will afford a basis for judging Mr. Hill's method. It seems to some observers that the relative concentrations of the different ions in a water and the chemical characteristics of different waters are a little more easily seen in Figs. 6 and 8. The properties Z_1, Z_2, Z_3, and Z_4 of Mr. Hill's system can be read from the

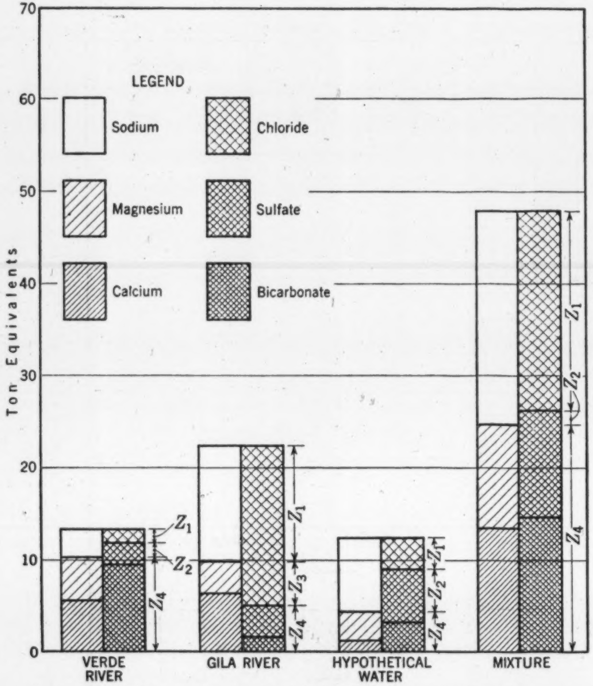

FIG. 8.—RIVER WATERS AND A MIXTURE OF RIVER WATERS, IN TON EQUIVALENTS

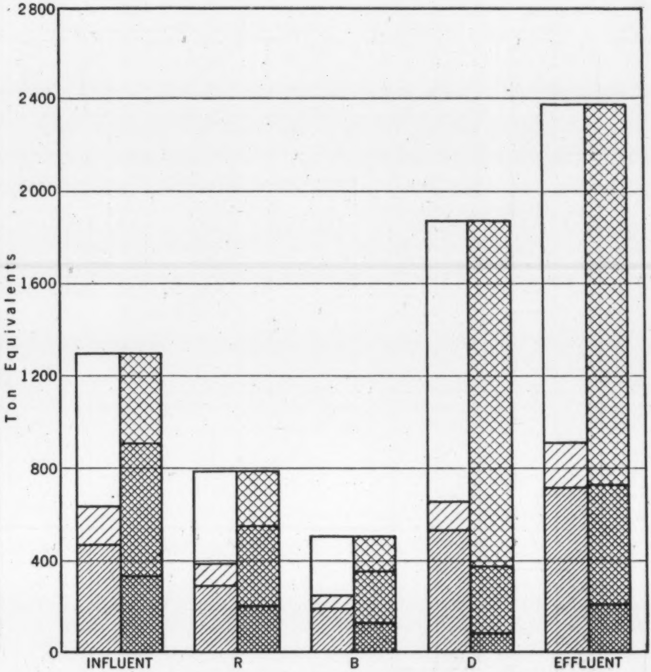

FIG. 9.—SALTS IN IRRIGATION WATERS, IN TON EQUIVALENTS

Survey diagrams. In equivalents per million the Z_1 term is the total quantity of sodium when this is less than the chloride, or the total quantity of chloride if the chloride is less than the sodium. The Z_4 property is the total quantity of bicarbonate and sulfate if this is less than the total of the calcium and magnesium, or the total of the calcium and magnesium if this is the smaller. The remainder of the Survey diagram between the Z_1 and the Z_2 parts is either Z_2 or Z_3 according to whether the chloride is less than, or greater than, the sodium. These measurements give the different properties in equivalents per million, which can be converted promptly to percentages by dividing by the total height of the diagram. The Z_1, Z_2, Z_3, and Z_4 properties are indicated in Figs. 6 and 8 which show the analyses of Fig. 1 and Tables 1 and 2.

It is customary to plot Geological Survey analyses in terms of equivalents per million, with the height indicating the concentration. When it is desired to emphasize the percentage composition this can be done by plotting all of the analyses to the same height and representing the concentration of total salts by the width of the diagram.[15]

Mixtures of Different Waters.—The fact that water *M* is a mixture of the other three (which is shown so clearly by the graphs in Table 2) would not be apparent from the analytical results tabulated in equivalents per million or shown in Geological Survey graphs. Granted that the one water is a mixture of the other three, the average person could probably compute the relative quantities of the component waters more quickly by the use of any three of the equations that may be written from the analytical results in the table.

Changes in Quality.—The analyses shown in Table 3 when plotted according to the Geological Survey system (Fig. 7) seem likely to give to the casual observer a clearer picture of the changes in character of the water along the river. Like Table 3, the Survey plot shows an increasing concentration of soluble salts from Del Norte to Fort Quitman. The water at Del Norte, of course, is excellent for all uses. Its total quantity of dissolved mineral matter is not large and the percentage of sodium is small. Increasing quantities of all the soluble salts appear at Lobatos and Otowi without much change in the chemical character of the waters, although the increase is more in calcium and magnesium and bicarbonate than in the other ingredients. From Otowi to San Marcial the water changes in chemical character. As far as Otowi the bicarbonate is the predominating anion and the calcium and magnesium together make up a very large percentage of the cations. To this point the water of the river is a typical calcium-bicarbonate water. The increase in bicarbonate from Otowi to San Marcial is insignificant. The largest relative increase is in sodium and sulfate although the chloride and calcium increase appreciably. The general character of the water remains practically unchanged from San Marcial through Leasburg. At El Paso, Fabens, and Fort Quitman, the sodium, sulfate, and chloride have increased greatly and the calcium has increased moderately, whereas the bicarbonate remains at about the same level.

The changes noted are almost universally characteristic of waters in irrigated areas. When water such as that at Otowi is evaporated to dryness and the residue is treated with distilled water, the calcium carbonate goes into solution slowly and in small quantities, whereas the sodium, magnesium, and calcium chlorides and sulfates go into solution rapidly. The calcium sulfate is not so soluble as the other salts and appears to have more of a tendency to be left behind in the land. These considerations appear more easily evident to the average observer from the Geological Survey graphs although they are all shown in Table 3.

[15] "The Significance of Geologic Conditions in Naval Petroleum Reserve No. 3, Wyo.," by W. T. Thom, Jr., and E. M. Spieker, *Professional Paper No. 163*, U. S. Geological Survey, Washington, D. C. (see section on the waters of the Salt Creek-Teapot Dome uplift, by Herman Stabler).

Valley Salt Balance.—In order to consider the valley salt balance shown in Table 4, the analyses of influent and effluent waters have been plotted according to the Geological Survey system in two units (Figs. 4 and 5). They are shown first in ton equivalents, as in Table 4. To obtain a better picture of the actual composition of the waters the two analyses are also plotted in equivalents per million. A glance at the diagrams in ton equivalents (Fig. 4) might suggest that the outgoing water was lower in bicarbonate than the incoming water. The diagrams in equivalents per million (Fig. 5) show that the effluent water is more concentrated than the influent water in every constituent. The fact that the effluent shows fewer tons of bicarbonate and sulfate than the influent is due in part to the fact that the volume of the effluent is only 27,000 acre-ft to 69,000 acre-ft for the influent.

The discussion by Mr. Hill centering around the imaginary water called "*A*" is ingenious and interesting and leads to practical conclusions that seem wholly sound. It would appear that substantially the same conclusions might be reached by direct consideration of tangible quantities without resort to an imaginary water.

From the table of analyses or from the Survey diagrams (Figs. 4 and 5) it can be seen readily that the effluent salts (or water) from the plot under consideration have a different character from the influent salts and water. The difference is not one of simple concentration as by evaporation of water, nor could it be brought about by the normal phenomena common in irrigated regions of precipitation of calcium carbonate or calcium sulfate. Besides the relative increase of sodium as compared to calcium, and of chloride as compared to bicarbonate, the diagrams show clearly, in equivalents per million, a shift of the sodium-magnesium boundary in relation to the chloride-sulfate boundary. In terms of hypothetical combinations the influent water carries sodium sulfate and no chloride of magnesium or calcium and the effluent water carries no sodium sulfate, but does have some magnesium chloride. In Mr. Hill's terms the diagrams of influent water show the Z_2 property and the effluent diagrams

TABLE 7.—ANALYSES OF INFLUENT AND EFFLUENT WATER FOR AN IRRIGATED VALLEY OVER A PERIOD OF ONE YEAR; WITH CERTAIN COMPUTATIONS FROM THE ANALYSES (RESULTS IN TON EQUIVALENTS)

show Z_3. The diagrams do not show any imaginary water or any loose unattached or unbalanced ions such as can be made to appear from the analytical results in Table 4.

It is recognized that an actual irrigated plot of 15,000 acres does not act like a glass vessel or like a bed of pure silica sand. The action with respect to applied water varies from spot to spot in the area. The analyses I and E in Table 4 give only an over-all picture of the relation of incoming and outgoing water and salts at a given time or over a given period. Assuming that the analyses are truly representative of actual conditions it appears that the influent water brought into the area more bicarbonate and sulfate than the effluent water removed, and that the effluent water took away more chloride than was brought in.

The simplest over-all solution of the problem would be to assume that some of the incoming calcium or magnesium bicarbonate and sulfate remained in the soil and that the outgoing water removed some calcium or magnesium chloride from the area. This can be set up as in Table 7 which shows, in ton equivalents:

I, the constituents of the influent water;
R, the tons of calcium bicarbonate and magnesium sulfate left in the area, out of the amount brought in by the influent water;
D, the tons of different constituents displaced from the store of soluble salts in the area at the beginning of the year;
$E' = I + D$, the sum of the influent salts and the salts displaced from storage in the ground (this might be called the over-all total of salts moved into and in the area);
$E = E' - R$, the difference between the tons of salts moved into and in the area and the tons of influent salts left in the ground; and
$G = D - R = E - I$, the apparent over-all removal of salts from the area.

TABLE 8.—RESIDUAL (R) AND DISPLACED (D) SALTS, AND APPARENT GAIN (G) IN AN IRRIGATED AREA DURING A PERIOD OF ONE YEAR

(Results in Ton Equivalents)

Ion	ASSUMPTION 1[a]			ASSUMPTION 2[b]			ASSUMPTION 3[c]			ASSUMPTION 4[d]

Cl	0	1,261	1,261	55	1,316	1,261	236	1,497	1,261	387	1,648	1,261
Sum	182	1,261	1,079	545	1,624	1,079	788	1,867	1,079	1,295	2,374	1,079

[a] No residual salts except the minimum bicarbonate and sulfate and no extra displaced salts except the equivalent calcium and magnesium chlorides. [b] The solution by the use of the imaginary water and diagrams of Mr. Hill's paper. [c] The salts in 27,000 acre-ft of influent water pass on through; the salts in 42,000 acre-ft of the influent remain in the area. [d] None of the influent salts leave the area; all the effluent salts come from the stored salts.

It is obvious that any number of solutions can be made by adding equal quantities to corresponding items in Cols. R and D. Quantity E will remain the same. The top limit will occur when *R* is the same as *I*. That will mean that none of the influent salt for the year was carried out of the area and the effluent salt was all from the store of soluble salts in the area.

Table 8 shows values of *R* and *D* for different assumptions. Fig. 9 shows, in ton equivalents, the influent salts in 69,000 acre-ft of water, the residual salts *R* from 42,000 acre-ft of the influent water, the salts carried through the area by 27,000 acre-ft of the influent water *B*, the salts taken up from the store in the area *D*, and the effluent which is the sum of *B* and *D* (see Assumption 3, Table 8).

The consideration of the relations between influent and effluent waters, whether by means of Mr. Hill's charts, by means of computation from the analyses, or by the Survey diagrams, points to the possible danger of accepting a false sense of security with reference to the salinity of lands in an irrigated area merely because the over-all salt balance seems to be favorable. The results show the need for continuous study of the character of the waters in contact with the soil as well as the influent and effluent waters for individual plots if salt damage to the land is to be avoided.

JOHN H. BLISS,[16] ASSOC. M. AM. SOC. C. E.—An interesting and ingenious method of plotting and classifying irrigation waters has been advanced by Mr. Hill. His geochemical chart is an excellent tool for portraying the relative amounts and characteristics of dissolved solids and for comparing differences in water supplies. It is also an aid in solving certain problems such as valley salt balance, although, in this connection, it does not appear to be quite so successful. The difficulty is not in the method but in the inadequacy of the basic data.

Because of the number of dissolved solids and the complexity of the effect of their active constituents upon crops and soils, it is obviously difficult, in a simple graph, to tell the entire story of a water's character and suitability for irrigation purposes. The problem is a complex one and the author is to be congratulated for his effort to simplify it and to standardize the method of reporting the results of water analyses.

By combining the strong sulfate ion with the weak carbonates and bicarbonates, rather than the chlorides and nitrates, Mr. Hill has departed somewhat from the Palmer method[2] of classification. By so doing he has tended to overlook the geologic significance of the Palmer classification in order to portray better the irrigation significance of natural waters.

The writer is somewhat familiar with the Rio Grande, one of the illustrative examples used by the author, and is particularly interested in his discussion of valley salt balance (upper El Paso Valley). Arriving at an indeterminate mathematical solution, Mr. Hill has solved the problem by reasonable deduction and has obtained an approximate answer to the true salt debits and credits in the area considered.

It is obvious that a permanent agriculture depends upon the maintenance of a salt balance in the root zone of cropped areas—that is, that as much of the undesirable dissolved constituents are removed from the root zone as are carried to it in the irrigation supply. The author has demonstrated that a balance between influent and effluent salts in an irrigated valley does not necessarily mean a favorable balance to the growing crops. The writer agrees, but rather questions the inference that, because unfavorable residual salts are being left behind somewhere in the soils of an area, the entire valley is affected adversely. In the illustrative case it would seem that many if not most of the residual salts were left in those areas of relatively impervious soils whose useful life as irrigated lands are automatically limited by their "tightness." In the remaining more porous soils of the valley, any residual accumulation may be removed easily from time to time by flushing the soil with excess quantities of water.

---

[16] Engr., State Engr's Office, Santa Fe, N. Mex.

Classifications of water according to their suitability for irrigation purposes have been advanced for certain limited areas. Realizing the pitfalls that surround any attempt at broad classification of waters, the writer feels that there is much work to be done along this line. C. S. Scofield[8] has presented a table of classes of irrigation water, which (he warns) are adopted for a definite irrigation region. The table sets up five classes of water from "excellent" to "unsuitable" and gives permissible limits of concentration of those constituents likely to be injurious to growing crops. For example, Class 5, or "unsuitable" irrigation water, is described in part as carrying more than 2,100 ppm of dissolved solids, more than 80% (of total positive ions) sodium, and more than 20 milligram equivalents each of sulfates and chlorides.

The following examples may be of interest and are included herein because the writer believes that they demonstrate the need for additional information on the effects of irrigation waters upon soils and crops.

The Pecos River in New Mexico and Texas carries one of the highest concentrations of dissolved solids of any western stream used for irrigation. For the three years 1938–1940, the water supply for the Carlsbad (N. Mex.) project, as measured on the Pecos River near the Artesia (N. Mex.) gaging station by the U. S. Geological Survey,[17] averaged 3,120 ppm of total dissolved solids, 37% sodium, and 28.8 and 18.5 milligram equivalents, respectively, of sulfates and chlorides. Water of this type and approximate average concentration has been applied on the project lands for almost fifty years with little apparent adverse effect except in those areas where drainage is difficult.

Texas projects, now combined in a single district under the Red Bluff reservoir, receive a much more unsuitable water supply than the Carlsbad project upstream. The quality of the district's irrigation supply as measured by the U. S. Geological Survey at the Orla (Tex.) gaging station below the reservoir, for the 1938–1940 period, averaged 4,520 ppm of total dissolved solids, 44% sodium, and 33.2% each of sulfates and chlorides. On the Pecos River at Red Bluff (N. Mex.) station above the reservoir, the sodium content for the same period averaged about 52%, a more representative value than that at Orla because the Orla data are affected by the holdover storage of the relatively good waters caught in the reservoir during the flood of June, 1937. Water of about the Red Bluff type and concentration has been used on Texas lands for many years. Considerable areas of heavy soils, particularly those in the flood channel along the river, have been "alkalied" and abandoned. However, large areas where natural or artificial drainage has been effective have been farmed successfully for many years with little apparent adverse effect.

---

[17] "Quality of Water," by C. S. Howard, W. F. White, Jr., and W. W. Hastings, U. S. Geological Survey—a section of the report, "Pecos River Joint Investigation," National Resources Planning Board, 1941.

TABLE 9.—CLASSIFICATION OF PECOS RIVER WATERS

Station	Palmer Classification				Hill classification (type)
	Class	Primary salinity	Secondary salinity	Secondary alkalinity	
Artesia...	3	37%	58%	5%	*b*I*a*
Red Bluff	3	52%	45%	3%	*d*VII*d*

The classification of these two waters according to the methods of Messrs. Palmer and Hill is shown in Table 9. It will be noted that the water at Red Bluff falls in Mr. Hill's Type VII, which he aptly calls "irrigation sewage."

Both waters, except as to sodium percentage, fall in Mr. Scofield's Class 5 or "unsuitable" irrigation water (assuming the Scofield classification to be applicable to this area). A favorable predominance of the earth bases over sodium and potassium exists in the Artesia water, but this advantage is lost at Red Bluff where sodium and potassium constitute more than 50% of the positive ions. There is insufficient evidence at this time to show what effect "base exchange" may have made upon the soils in either area.

How long successful irrigation agriculture can endure, particularly in the Red Bluff district, under the continued use of such highly concentrated, inferior quality water remains to be seen. It would appear, however, that even poor quality saline water may be used more or less successfully for irrigation purposes for considerable periods of time if the excess salts are flushed away from time to time and thus prevented from accumulating in the root zone of growing crops. There is a definite need for additional study of this complex problem.

RAYMOND A. HILL,[18] M. AM. SOC. C. E.—It is significant that most of the discussions of this paper contain an endorsement of the writer's conclusion regarding the necessity for much more study of the problem of salinity by irrigation engineers and others concerned with the use of water, even if the variance in views presented in these discussions did not in itself make this apparent. The writer regrets that so much of the discussion was directed toward the tool offered the engineering profession and so little toward its application in solving the problems of the engineer and the agriculturalist.

Geochemical Classification.—It must be recognized that the system of classification suggested by Chase Palmer more than thirty years ago has had very limited application and has remained largely a matter of mystery to engineers.[2] The writer realizes that his modification of that system, although perhaps better adapted for use in the interpretation of analyses of water used in agriculture, will enjoy no better fate. Neither is it believed that the classifications suggested by W. F. Langelier and H. F. Ludwig, Jun. Am. Soc. C. E., in their discussion published elsewhere[19] will come into more general usage.

---

[18] Cons. Engr. (Leeds, Hill, Barnard & Jewett), Los Angeles, Calif.

[19] "Graphical Methods for Indicating the Mineral Character of Natural Waters," by W. F. Langelier and H. F. Ludwig, *Journal*, A.W.W.A., March, 1942, p. 335.

All three systems of classification depend upon the relative concentration of various combinations of ions which are not easy to remember and which have little significance to the engineer. Evidently Mr. Scofield was correct when he stated that there exists among hydrologists a difference of opinion as to whether Palmer's classification should be retained in use even if revised.

It is important, however, to develop some system of designation of waters of different character. Any such system must be based upon the predominance of one or another of the various ions; otherwise, the designation will be without significance. On the other hand, the system must be simple and easily remembered by the engineer as well as the chemist; otherwise the terminology can never be used generally. It has since occurred to the writer that the general purpose of any geochemical classification could best be accomplished by avoiding any grouping of ions and by merely defining the predominant cation and the predominant anion, if any, by the capital letters *A*, *B*, *C*, and *D* for the positive ions, and the lower-case letters *a*, *b*, *c*, and *d* for the negative ions, as follows:

A—Any water in which calcium constitutes more than one half of the cations;

B—Any water in which magnesium constitutes more than one half of the cations;

C—Any water in which the sodium and potassium ions constitute more than one half of the cations;

D—Any water in which *A*, *B*, or *C* does not constitute more than 50% of the total cations;

a—Any water in which the carbonate and bicarbonate ions constitute more than one half of the anions;

b—Any water in which the sulfate ions constitute more than one half of the total anions;

c—Any water in which the chloride and nitrate ions constitute more than one half of the anions; and

d—Any water in which *a*, *b*, or *c* does not constitute more than 50% of the total anions.

There are, of course, sixteen possible two-letter combinations, which should be sufficient for descriptive purposes; for example, any water containing a predominance of calcium carbonate or bicarbonate would be designated as Type *Aa*; water from Salt River in Arizona would be designated as Type *Cc*, indicating that most of the dissolved solids were sodium chloride; and the sample of Verde River water, for which the analysis is given in Table 1, would be of Type *Da*.

Bar Diagrams.—Mr. Collins and Mr. Stabler both indicate their preference for bar diagrams as a means of showing graphically the character and concentration of salts in any water. Mr. Collins gives several illustrations of the use of such diagrams where the concentration is indicated by the length of the bar. Mr. Stabler, on the other hand, shows the concentration by the width of the bar and maintains the same over-all length in each case. The use of a graph having bars of different heights to show the relative concentration of the principal ions and the relative total concentration of different waters is particularly advantageous when the subject matter is to be considered by some lay body. For example, the differences in the quality and character of water available from various sources to communities northeast of Los Angeles, Calif., are obvious from Fig. 10, but no group of laymen could be expected to interpret the corresponding plotted points on a geochemical chart, regardless of its form.

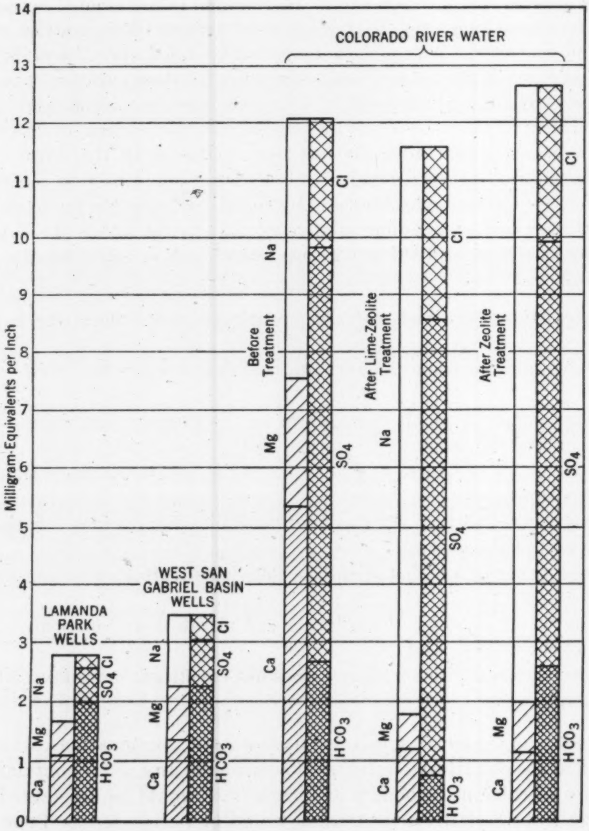

Fig. 10.—Comparative Quality of Water from Typical Recent Analyses

In general, it may be said that the bar diagram is well adapted to the presentation of the results of some study, but it is believed that the point representation possible on a geochemical chart is better adapted to the study itself.

Mixtures of Waters.—The writer accepts the statement of Mr. Collins that, if one water is actually a mixture of three others, the average person probably could compute the relative quantities of the component waters more quickly by the use of any three of the equations that may be written from the analytical results in the table. This was the case with the data presented in Table 2, which represented a true mixture for purposes of illustration. However, a true mixture rarely is found in nature, and even if one water is known to be a mixture of two or more waters from different sources, there will usually be sufficient inaccuracy in the sampling or in the chemical analyses of the samples to prevent a direct and precise analytical solution.

The practical limitations involved in any problem of mixtures are illustrated by the condition that prevails at Granite Reef Dam, the point of diversion into the Arizona Canal and the South Canal, both of which serve the Salt River Project of Arizona. The Verde River enters the Salt River from the north about 3 miles east of Granite Reef, and the supply diverted is composed almost entirely of water released from reservoirs on the two streams. Between the confluence of the streams and the point of diversion there appears to be full opportunity for the two waters to mix thoroughly, yet it is obvious from the data in Table 10 that this is not true.

TABLE 10.—CHEMICAL ANALYSES OF VERDE RIVER AND SALT RIVER WATERS; COMPOSITE SAMPLES FOR NOVEMBER, 1940

(Units: Equivalents per Million, epm)

Points	River	Location	CATIONS			Σ	ANIONS		
			Ca	Mg	Na+K		H CO_3	SO_4	Cl+NO_3
V	Verde River	Below Bartlett Dam	2.41	2.00	1.24	5.65	4.21	0.91	0.53
S	Salt River	Below Stewart Mountain Dam	2.72	1.35	10.27	14.34	2.60	1.22	10.52
M_A	Arizona Canal	At Granite Reef Dam	2.32	1.75	3.29	7.36	3.50	0.94	2.92
M_S	South Canal	At Granite Reef Dam	2.46	1.77	4.45	8.68	3.51	1.04	4.13

When these data are plotted on the geochemical chart (Fig. 11), it is evident that the water diverted into each canal is almost a true mixture of the supply from the Verde River and from the Salt River, but that the proportion of Verde River water taken into the Arizona Canal is greater than the proportion taken into the South Canal. The relative amounts of Verde River water taken into each of the canals can be computed graphically, as indicated in Fig. 11, or by the use of simultaneous equations, assuming a true mixture in each case. No precise solution is possible under the circumstances, but evidently about 77% of the water diverted at the north end of Granite Reef Dam originated in the Verde River, as compared with about 65% of the water diverted from the other side of the river.

The divergence between the plotted positions of the samples from the Arizona Canal and from the South Canal, and the divergence of both from the position of a true mixture, are illustrative of the fact that the character of water in a river cannot be judged from samples taken at one point or at one time.

Alternate Form of Geochemical Chart.—The data given in Table 10 are also shown in Fig. 12, which is in the form of the geochemical chart required to conform with Palmer's classification. The same methods of graphical analysis, which are applicable to the geochemical chart shown in Fig. 1, can be used on this alternate form, and the choice between them depends largely upon the individual and the problem at hand.

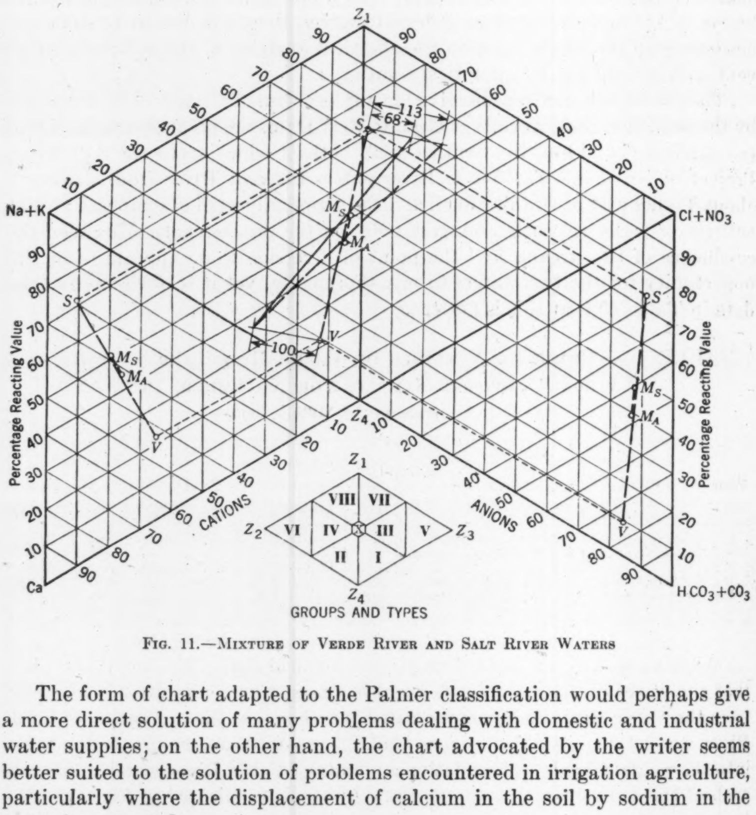

FIG. 11.—MIXTURE OF VERDE RIVER AND SALT RIVER WATERS

The form of chart adapted to the Palmer classification would perhaps give a more direct solution of many problems dealing with domestic and industrial water supplies; on the other hand, the chart advocated by the writer seems better suited to the solution of problems encountered in irrigation agriculture, particularly where the displacement of calcium in the soil by sodium in the water is suspected.

Valley Salt Balance.—Mr Bliss properly pointed out that the solution of the valley salt balance problem gives an average result, and that, although worse conditions will occur locally, the situation may be satisfactory generally. However, if the salt balance is adverse for the area as a whole, the danger of salt accumulation is greater than if the opposite is true.

Mr. Collins referred to the imaginary water called "*A*" in the writer's opening discussion of this matter. The value of so considering the difference between the quantities of salt in the influent water and the quantities of salt in the effluent water is largely a matter of convenience, but where the point *A* falls outside of the figure, it is immediately apparent that a simple difference between the influent quantities and the effluent quantities cannot be used. Although it is true that substantially the same conclusion (as stated by Mr. Collins) might be reached by direct consideration of tangible quantities, it is believed that a more rational solution of the complex problem can be had by use of a geochemical diagram upon which can be shown all of the analyses required for the solution.

FIG. 12.—MIXTURE OF VERDE RIVER AND SALT RIVER WATERS (ALTERNATE ANALYSIS)

For example, Assumption 1 in Table 8 requires that there be no displacement from the soil or from the ground water of any chloride ion, and at the same time that the salts left behind should include no chloride. This is contrary to the statement of Mr. Collins, to wit: "It is recognized that an actual irrigated plot of 15,000 acres does not act like a glass vessel or like a bed of pure silica sand." Assumption 3 in Table 8 likewise depends upon an improbable premise, which could be true only if 27,000 acre-ft of influent water passed through the canal system without being diverted, and all of the remainder of the water was consumed, leaving the salts in the soil. Assumption

4 in Table 8 is merely an extension of Assumption 3 and clearly could not be the case in fact.

Messrs. Langelier and Ludwig state[19] their agreement with Mr. Collins but, in doing so, fail to realize that in the solution of the problem given in Table 4 the writer attempted to weight the various factors involved, including the facts that there was no percolate from some irrigated fields, that all of the canal seepage could not have reached the effluent drain within the period of time under consideration, and that in other parts of the area where there was free drainage probably no chlorides were left behind.

Although any problem susceptible of graphical analysis may be solved mathematically, it is believed that where judgment is so large a factor, as in this type of problem, there is much to be gained by the use of graphical methods that enable the assumptions to be visualized.

Salt Tolerance.—It was suggested that someone proceed further and investigate the effect of different kinds of water on soils and on plant growth. Mr. Scofield briefly did so, describing the general effect of waters of different character and, to some extent, the specific effect of certain ions.

Mr. Stabler reviewed a method outlined by him about thirty years ago[6] which, as he states, is far from adequate but which has proved useful in some cases. It is hoped that Mr. Stabler, or someone following in his steps, will develop more accurate formulas on the basis of the wealth of information and experience now available. It is suggested that, in any new formula patterned upon the work of Mr. Stabler, the index should be the reciprocal of his alkali coefficient, as modified, so that the direction will be from low values for good water to large values for bad water, as is generally the case when the total concentration of salts is used as an index of quality.

Mr. Lewis comments upon the carbonate and bicarbonate content as being of particular importance in agricultural practice. Reference should be made to the statement by Mr. Scofield on this point—namely,

> "There is much to be found in literature about the harmfulness of the carbonate-bicarbonate constituent, the so-called 'black alkali.' The injurious potentialities of this constituent are overrated. Most of the trouble allegedly due to black alkali is caused by sodium, and sodium is no less harmful when it occurs with sulfate, chloride, or nitrate than when it occurs with carbonate or bicarbonate."

Necessity for Further Study.—In closing, the author wishes to repeat his statement, concurred in by most discussers, that "Much more study of these problems by irrigation engineers and agriculturalists is needed, to the end that successful irrigation agriculture may be permanent rather than temporary."

A DIRECT METHOD OF FLOOD ROUTING

By C. O. Wisler,[1] M. Am. Soc. C. E., and E. F. Brater,[2]
Jun. Am. Soc. C. E.

With Discussion by Messrs. Ray K. Linsley, Jr., Harold C. Hickman, Robert B. Horonjeff and Herbert G. Crowle, L. K. Sherman, Alfred L. Brosio, W. B. Langbein, Fred E. Tatum, H. C. Woster, and C. O. Wisler and E. F. Brater.

Synopsis

A method of flood routing is described herein, the successful use of which depends only upon the availability of dependable stream-flow records during a typical flood at various points on the main stream or on the tributaries whose flow is to be routed downstream. No cross sections of stream channel or velocities of flow are required. Nor are discharge records on all of the tributaries needed. A hydrograph of inflow from the unmeasured area is directly computed. This flow and that at each of the upstream stations is then routed downstream.

These routed flows show the extent to which each of the upper tributaries contribute to the flood peak at each downstream point. A check on the accuracy of the results is provided by adding the routed flows and comparing the resulting hydrograph with the actual records.

The entire procedure is based upon the storage equation and upon the principle that, for all high stages, there is a straight-line relationship between the volume of storage contained in any reach of river channel and the sum of the inflow rate at the upper end and the outflow rate at the lower end of that reach. Except perhaps for unusual channel conditions, this relationship holds true.

Introduction

In large drainage basins, floods usually wreak their greatest havoc at some downstream point. At any instant the total flow at this point comprises waters contributed by many different tributaries. The percentage of the total flow occurring at any instant that is contributed by any single tributary is constantly changing throughout the flood period. Perhaps the maximum flow from no tributary reaches this point at the same time that the total combined flow

---

Note.—Published in June, 1941, *Proceedings*.

[1] Prof., Hydr. Eng., Univ. of Michigan, Ann Arbor, Mich.

[2] Asst. Prof., Civ. Eng., Univ. of Michigan, Ann Arbor, Mich.

becomes the maximum. The flood waters from some of the tributaries may have passed this point long before the peak stage occurs, whereas the waters from some of the more remote tributaries do not arrive until after that stage has passed.

In all studies in which it is proposed to secure improved conditions by reducing the flood peak through the use of reservoirs, by reforestation, or by means other than local protective measures, such as levees and flood walls, it is essential to know to what extent each of the several tributaries contributes to the resulting flood peak. Without this information no intelligent planning of flood control is possible. With a hope of reducing the downstream flood peak, vast expenditures might be made on a certain tributary, the net result of which would actually be negligible or even damaging instead of beneficial.

The writers' interest in this problem was aroused by the Potomac River flood-control studies of the U. S. Department of Agriculture. These studies are being made as an inter-bureau endeavor by the Forest Service, Soil Conservation Service, and Bureau of Agricultural Economics under the chairmanship of the Appalachian Forest Experiment Station at Asheville, N. C. In connection with that work this method of flood routing was developed and successfully applied to the Shenandoah River, a tributary of the Potomac, and later to the Monongahela River in West Virginia.

It is believed that the clearest presentation of this method of flood routing can be made by means of an illustrative example. Because of the excellent discharge records that are available and because of a complication resulting from a subsequent rain that fell during the recession period of the hydrograph, the March, 1936, flood on the Monongahela has been selected for a detailed presentation.

The Monongahela River rises in the north central part of West Virginia, and flows in a general northerly direction through Morgantown, W. Va., which is a few miles south of the Pennsylvania boundary (see Fig. 1). The drainage area above Morgantown is 2,670 sq miles. The principal tributary is the Tygart River which empties into the Monongahela approximately thirty miles upstream from Morgantown. The drainage area above Fetterman, W. Va. (later a part of Grafton, W. Va.), which is about twenty miles above the mouth of the Tygart, is 1,340 sq miles. Discharge records taken at 2-hr intervals at Morgantown and Fetterman are published in U. S. Geological Survey *Water Supply Paper No. 800.*

The first operation described in the paper is the derivation of the hydrograph of inflow into the intervening area between Fetterman and Morgantown. This inflow and the measured discharge at Fetterman are then routed separately to Morgantown. The procedure for determining the effect at Morgantown of flood-control measures on the Tygart is discussed, and a method of determining corresponding effects at other points on the stream is suggested. Finally, the results of two more applications of the method are briefly presented.

DETERMINATION OF UNMEASURED INFLOW

The first step in the solution of this problem lies in the determination of the hydrograph of channel inflow from the intervening area. The intervening

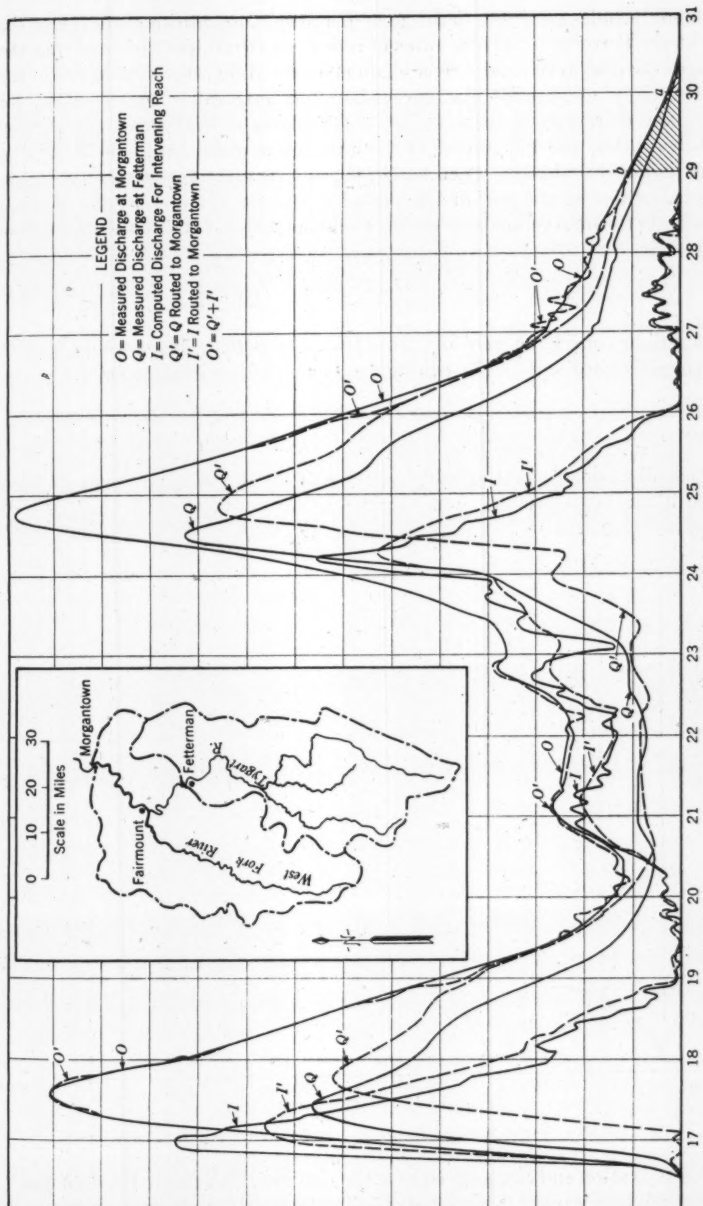

FIG. 1.—HYDROGRAPHS OF SURFACE RUNOFF, WATERSHED OF THE MONONGAHELA RIVER

area here includes all of the drainage area above Morgantown exclusive of the area above Fetterman. These rates of inflow are determined by applying the storage equation to the entire river channel above Morgantown exclusive of the channel above Fetterman for successive 2-hr intervals. In so doing, let Q_0, O_0, and S_0 represent, respectively, the discharge at Fetterman, the outflow at Morgantown, and the storage in the intervening reach, all at the beginning of the period considered. Then let Q_1, O_1, and S_1 represent, respectively, the same quantities at the end of the period. Also let I represent the average inflow from the intervening area during the same period. The resulting storage equation is

$$S_0 + 2\left(\frac{Q_0 + Q_1}{2}\right) + 2\,I - 2\left(\frac{O_0 + O_1}{2}\right) = S_1 \ldots\ldots\ldots\ldots (1)$$

If the periods considered were any other than 2-hr periods, Eq. 1 would have to be changed accordingly. The equation may be written in the form

$$I = \frac{S_1 + O_0 + O_1 - (S_0 + Q_0 + Q_1)}{2} \ldots\ldots\ldots\ldots\ldots (2)$$

in which all quantities on the right-hand side of the equation are known except S_1 and it can be determined from a curve of relation between S and $(Q + O)$ shown in Fig. 2.

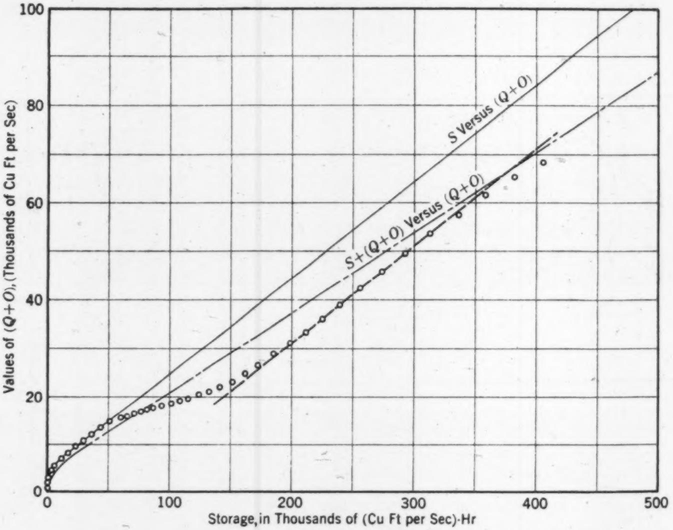

Fig. 2.—Relation Between $(Q + O)$ and the Storage in the Intervening Reach

The derivation and characteristics of the curve of relationship between S and $(Q + O)$ will be discussed in some detail. The storage in the intervening reach is obtained by making use of a principle that was apparently first utilized by R. E.

Horton,[3] M. Am. Soc. C. E.—namely, that at any time after the point of contraflexure occurs on the recession side of a hydrograph of surface runoff, the total volume of channel storage is equal to the total area beneath the hydrograph subsequent to that time. For instance, in Fig. 1, the total volume of channel storage above Morgantown at noon on the 30th is equal to the area of the shaded part beneath the hydrograph marked *O* and to the right of *a*. Also the total channel storage at noon on the 29th is represented by the shaded area to the right of *b*, etc. In a similar manner, the total channel storage occurring at any instant in the Tygart River above Fetterman can be determined from the hydrograph *Q*, Fig. 1. By deducting the channel storage above Fetterman occurring at any instant from the simultaneous storage above Morgantown, the volume of channel storage contained in the intervening reach is obtained.

For any given reach of river channel, there is a definite relationship between the volume of channel storage contained therein at any instant and the sum of the simultaneous discharge rates at the two ends of the reach. Such a relationship exists because *Q* is proportional to the river stage at the upper end of the reach, *O* is proportional to the stage at the lower end, and therefore $(Q + O)$ is proportional to the average stage which in turn depends upon the volume stored. When these two quantities are plotted on ordinary cross-section paper, the graph is a straight line, except for the lower stages. This result is most fortunate because if this relationship did not plot as a straight line, it would be extremely difficult to extend the curve into the higher stages in such a manner as to eliminate the effects of overland flow. It could probably be done only by trial and error and would be a long and laborious process.

In the foregoing, the fact was stated that Mr. Horton's method of determining the volume of channel storage from the area beneath the hydrograph is applicable only back to the point of contraflexure. It is believed that overland flow ceases at or near this point. This concept is substantiated by the experience of the writers that, in every application made to date (1941), this straight-line relationship holds true only for values derived to the right of the point of contraflexure. If the derivation is extended much beyond that point, the storage values all fall to the right of the straight line, indicating that some overland flow is being included as channel storage. As an illustration, it may be noted that in Fig. 2 the points fall to the right of the straight line for values of $(Q + O)$ greater than 58,000 cu ft per sec. It may be seen from Fig. 1 that $(Q + O)$ is equal to 58,000 at noon on March 26, which is approximately at the point of contraflexure of the curves of *Q* and *O*.

To obtain the hydrographs of surface runoff at Morgantown and at Fetterman (see graphs *O* and *Q*, Fig. 1) it was necessary to deduct the ground-water flows from the total discharges. This was done by drawing, on the hydrographs of total flow, straight lines connecting the points at which surface runoff appeared to start and end. Although this procedure is perhaps not accurate, it is sufficiently correct for this purpose.

---

[3] "Surface Runoff Phenomena," by Robert E. Horton, *Publication 101*, Horton Hydrological Lab., Voorheesville, N. Y., 1935, p. 35.

In Fig. 2 the points indicated by small circles were obtained by plotting the value of $(Q + O)$ at any instant as shown in Fig. 1 against the area between the curves Q and O subsequent to that instant. For example, at 2:00 p.m. on the 29th, $O = 4{,}800$, $Q = 3{,}540$, and $S = 18{,}840$ (cu ft per sec)-hr, the latter value representing the area between the graphs O and Q (Fig. 1) after 2:00 p.m. on the 29th. At noon on the 29th, $O = 5{,}200$, $Q = 3{,}720$, and therefore

$$S = 18{,}840 + 2\left(\frac{5{,}200 - 3{,}720 + 4{,}800 - 3{,}540}{2}\right) = 21{,}580 \text{ (cu ft per sec)-hr.}$$

In this same manner the other points indicated by circles in Fig. 2 were obtained.

It should be observed that for values of $(Q + O)$ between 8,000 and 15,000, and also between 30,000 and 55,000, these points fall on two straight lines and furthermore that these lines are parallel. Now the value of $(Q + O)$ was 30,000 at 4:00 a.m. on the 27th and 15,000 at 6:00 p.m. on the 28th. During the intervening period channel inflow was taking place as a result of a subsequent rain that fell during the recession period. This channel inflow from the intervening area amounts to about 65,000 (cu ft per sec)-hr and is represented by the area under the hydrograph I during this period. Its net effect is to move the S versus $(Q + O)$-curve horizontally to the right a distance representing 65,000 (cu ft per sec)-hr. Had it not been for this subsequent channel inflow, the curve of relation between S and $(Q + O)$ would have extended beyond the value of $(Q + O) = 15{,}000$ cu ft per sec as shown by the solid line in Fig. 2. This solid line, therefore, is taken as the curve of relation between S and $(Q + O)$. Since both Q and O are known, it is possible to determine the values of S corresponding to any value of $(Q + O)$ and thus solve equation 2 for I. The graph of I (Fig. 1) was obtained in this manner.

A check on the accuracy of these computations can be made by deducting the total discharge at Fetterman from the total outflow at Morgantown and comparing this quantity with the total computed inflow from the intervening area. In this case the total outflow at Morgantown is equal to 3,894,200 (cu ft per sec)-hr, and the total discharge at Fetterman is 2,326,900 (cu ft per sec)-hr. The difference between these two quantities is 1,567,300 (cu ft per sec)-hr as compared with a total computed inflow of 1,566,900 (cu ft per sec)-hr.

Such a remarkably close agreement should not be expected in all cases. Nevertheless, the maximum error experienced by the writers to date has amounted to about 6%. In such cases all computed inflows from the intervening area may be corrected by a constant percentage in order to make them equal to the difference between Q and O. If the error should be considered to be excessive, however, it might be better to reconstruct the S versus $(Q + O)$-curve by trial until the error virtually disappears. This latter procedure would have to be followed if the stations were separated by such a great distance that this curve would perhaps deviate from a straight line.

ROUTING *Q* AND *I* THROUGH TO MORGANTOWN

The next step in the solution of this problem is the determination of the hydrographs at Morgantown resulting from (1) the foregoing discharge rates at Fetterman, and (2) the inflows from the intervening area. In other words, when do the peak flows from these two sources reach Morgantown? What are their magnitudes? How are the total flows distributed at that point? In answering these questions, the intervening channel is considered to be a storage reservoir through which the flow from each source is routed separately and independently of the other. A check upon the accuracy of the results is then obtained by combining these two graphs of routed flows at Morgantown and comparing the resulting hydrograph with the actual recorded hydrograph at that point.

First, route the Fetterman discharge. For this purpose, the inflow from the intervening area, I, will be ignored and the storage formula (Eq. 1) may be written as follows:

$$S_0 + Q_0 + Q_1 - O_0 = S_1 + O_1 \qquad (3)$$

All of the quantities on the left-hand side are known, thus giving the sum of S_1 and O_1 but not their individual values. These may be obtained by adding Q_1 to each side of the equation, thus giving Eq. 4,

$$S_0 + Q_0 + 2\,Q_1 - O_0 = S_1 + (Q_1 + O_1) \qquad (4)$$

which can be solved by means of a curve of relation between $(Q + O)$ and $S + (Q + O)$, as shown in Fig. 2. Since Q is known, O can be obtained, and finally S. These values of S_1, Q_1, and O_1 become the values of S_0, Q_0, and O_0 for the next period and the computations become continuous.

It should be observed that O here takes on a significance quite different from that which it possessed previously. Heretofore it represented the total recorded outflow at Morgantown, whereas it now represents the computed outflow at Morgantown resulting from the flow Q at Fetterman. In Fig. 1 this quantity is designated as Q' and the same symbol would be used here were it not for the confusion that would result from the use of Fig. 2.

In routing I through to Morgantown, since Q is now ignored completely, Eq. 1 may be written

$$S_0 + 2\,I - O_0 = S_1 + O_1 \qquad (5)$$

In this equation O again takes on a new significance, now representing the computed outflow at Morgantown resulting from the inflow from the intervening area. In the solution of Eq. 5 all the quantities on the left-hand side are known, and therefore $S_1 + O_1$ is known. Referring now to Fig. 2, since Q is ignored, the dash-dot curve becomes one of O versus $(S + O)$, and from it O can be determined, and finally S. These values of O_1 and S_1 then become the values of O_0 and S_0 for the next period and the procedure is repeated. These outflows at Morgantown resulting from the inflows from the intervening area are shown graphically in Fig. 1 by the dotted line marked I'.

By combining the graphs I' and Q', Fig. 1, the outflow graph, O', at Morgantown is obtained. The agreement of this graph with the actual hydrograph O is quite remarkable, especially throughout the higher stages during which the greatest need exists for accurate and dependable results.

Reduction of Flood Peak at Morgantown

After the flood of March, 1936, a dam and storage reservoir were constructed on the Tygart River near Fetterman. The effectiveness with which the storage thus provided may be expected to reduce the flood peak at Morgantown or at any other downstream point depends upon the rules that are formulated governing the operation of that storage. The reservoir outflows resulting from any such proposed set of rules can be computed and this revised Q can then be routed through and the reduction benefits determined at points downstream.

On the other hand, if it is proposed to reduce the flood flows at the upper station by terracing, by change in land use, or by some other means, then a revised hydrograph of Q at that point must necessarily be based on judgment.

After the revised Fetterman hydrograph has been routed through to Morgantown, this revised graph of Q' can be combined with I' to give a revised graph of O'. Making use of the stage-discharge relationship curve this revised O' hydrograph can be converted into a stage graph which, upon comparison with the original records, will show the amount of reduction in stage at Morgantown resulting from the flood control improvements made above Fetterman. A similar procedure can be followed for determining the amount of stage reduction that can be effected at Morgantown from any contemplated improvements in the intervening area.

Reduction of Peak at Other Points

One is not always so fortunate as to have discharge records available at all damage centers where flood reduction benefits are to be appraised. So frequently are such records missing that it seems desirable to summarize, briefly, a procedure that may be followed in such cases. Suppose, for instance, that the damage center is at Fairmont, West Virginia, which is just below the junction of the Tygart and the Monongahela. The reduction at this point may be found as follows:

(1) Determine the inflow from the intervening area between Fetterman and Morgantown and route this flow and the Q at Fetterman through to Morgantown in the manner already described.

(2) Measure the intervening area above Fairmont and find the percentage that this area is of the total intervening area above Morgantown. Then apply this percentage to the various inflows already computed (shown graphically as I, Fig. 1) to obtain a hydrograph of I for the intervening area above Fairmont.

(3) Construct a stage-discharge relationship curve for Fairmont based upon any discharge measurements that may be obtainable during normal and low stages and upon high water-marks for floods whose discharges are known at Fetterman and at Morgantown. If the approximate stage at Fairmont corresponding to zero discharge can be determined, a satisfactory stage-discharge curve should be obtained by plotting the foregoing data on logarithmic paper.

(4) A curve must now be derived showing the relation between channel storage in the intervening reach above Fairmont and the sum of the discharges at Fetterman and at Fairmont. For any value of $(Q + O)$ the total channel

storage above Fairmont can be closely approximated by prorating the total storage above Morgantown in the ratio of the drainage area above Fairmont to that above Morgantown. For the ordinates of this curve Q remains the same as before, but O must also be reduced in the ratio of these two drainage areas. An auxiliary curve showing the relation between $(Q + O)$ and $S + (Q + O)$ should now be plotted. With the aid of this curve and the storage equation, the outflows at Fairmont can be found in a manner previously described.

From this point, the procedure for the determination of the effect of a storage reservoir or other proposed improvement, either above Fetterman or in the intervening area, is the same as has already been described.

Applications to Shenandoah River

In order to test this method of flood routing for different types of stream pattern and shapes of drainage basin, two other routings were made, both on the Shenandoah River in Virginia. A comparison of the watersheds in Figs. 1 and 3, together with Table 1, shows these differences of conditions quite clearly.

For these Shenandoah tests a flood was used that occurred in March, 1936, at the same time as the preceding one used on the Monongahela. The discharge records are also obtained from *Water Supply Paper No. 800.*

In determing the inflow occurring at any instant from the intervening area above Lynnwood the sum of the channel storages existing simultaneously above the stations on North River at Burketown, Middle River near Grottoes, and South River at Harriston was deducted from the total channel storage above Lynnwood. This storage was plotted against the sum of the outflow at Lynnwood and the discharges at the upper three stations. These three discharages were then routed simultaneously through to Lynnwood although it is believed that the same result would have been obtained had each been routed separately and then combined later. The Lynnwood discharge, and also that from the intervening area below Lynnwood, were then routed to Front Royal.

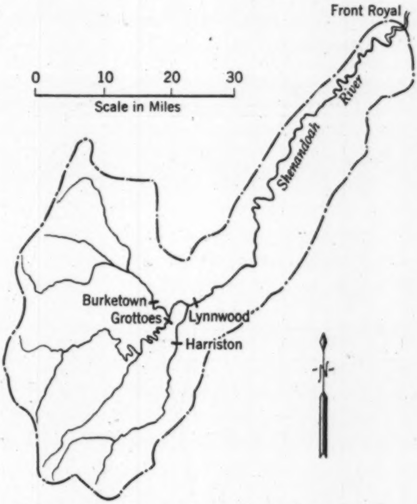

Fig. 3.—Watershed of the Shenandoah River, Above Front Royal, Va.

The results of these two routings are shown in Fig. 4. At Lynnwood the sum of the routed flows agrees almost perfectly with the actual records. At Front Royal, however, the agreement is not as good, although it can hardly be classed as poor.

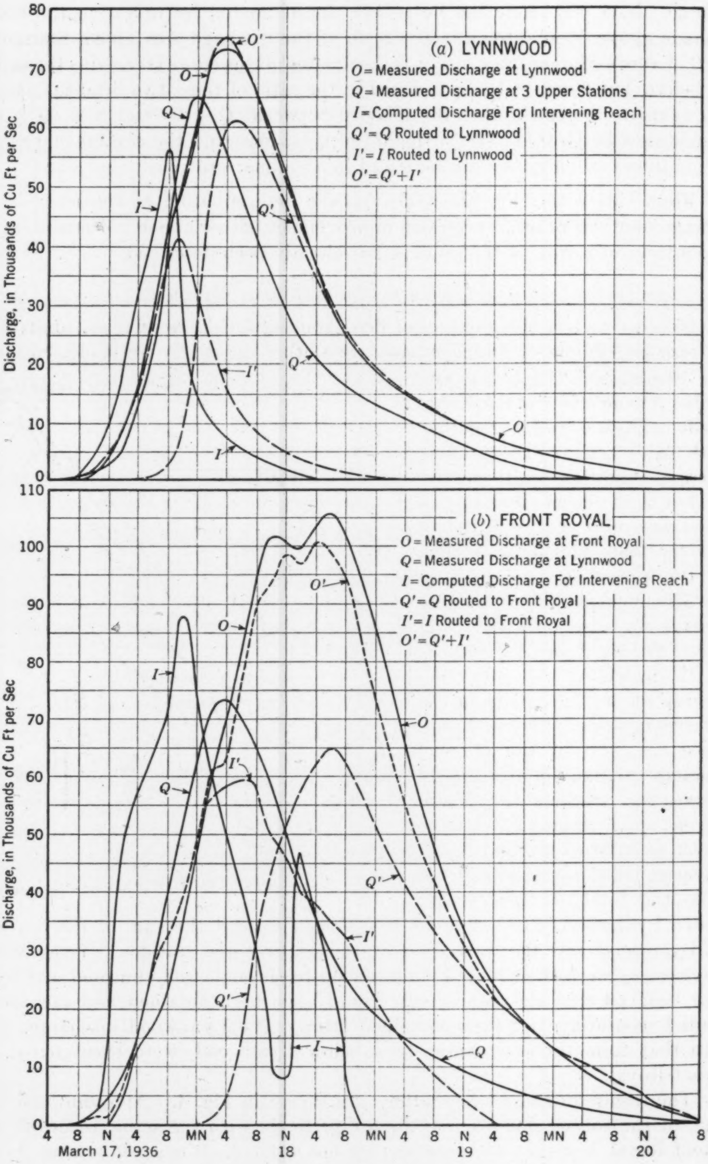

FIG. 4.—HYDROGRAPHS OF SURFACE RUNOFF

TABLE 1.—WATERSHED CHARACTERISTICS

Lower station	Area, in sq miles	Upper station	Area, in sq miles	INTERVENING:	
				Distance, in miles	Area, in sq miles
Morgantown, W. Va.	2,670	Fetterman, W. Va.	1,340	50	1,330[a]
Lynnwood, Va.	1,076	Burketown, Va. Grottoes, Va. Harriston, Va.	381 360 222	15 10 10	113[b]
Front Royal, Va.	1,638	Lynnwood, Va.	1,076	70	562[c]

[a] Long and nearly parallel with upper basin. [b] Wide, short, and entirely downstream from upper basins. [c] Long, narrow, and entirely downstream from upper basin.

The probable reason for the failure to obtain better results at Front Royal may be found in the following statement:[4]

> "Stage-discharge relation.—(At Front Royal) Defined by current-meter measurements below 25,000 second-feet; extended to peak stage by velocity-area study near control section, slope-area determination, and comparison of peak discharge and total run-off of flood with other records on the same or neighboring streams. Discharge may have been affected by backwater from North Fork of Shenandoah River from about 8 p.m. Mar. 17 to about 2 p.m. Mar. 18. Discharge at 8 a.m. Mar. 18 may have been about 75,000 second-feet instead of 99,900 second-feet. Volume of run-off during the flood rise would be reduced by a small percentage."

Because of the backwater to which reference is made in the foregoing notes, and also because of the fact that it was necessary to extend the discharge curve from 25,000 cu ft per sec to 113,000 cu ft per sec, it is easily conceivable that the entire disagreement between the computed graph O' and the hydrograph O, Fig. 4(*b*), may be due to faulty discharge records at Front Royal.

CONCLUSION

It is believed that, except possibly under unusual channel conditions, the curve of relationship between channel storage in the intervening reach and the sum of the discharges at the two ends of the reach is a straight line for the normal and high stages of the river. This straight line together with a supplementary curve expressing the relationship between $(Q + O)$ and $S + (Q + O)$ permits the direct determination of: (*a*) A hydrograph of channel inflow from the intervening area; and (*b*) the routed flows from the upper area and from the intervening area as they appear at the lower station. A positive check on the accuracy of both of these determinations can be made quickly and easily.

Furthermore, it is the belief of the writers that the accuracy of the results that can be obtained by this method of flood routing depends almost entirely upon the availability of: (*a*) Good stage-discharge relationship curves at various points on the stream; and (*b*) an actual flood record. With these data at hand, either the known flood or any hypothetical flood can then be routed downstream, and the benefits that may be expected from any proposed system of storage reservoirs or other plan of flood control can be determined definitely, and the benefits can be weighed against the cost.

DISCUSSION

Ray K. Linsley, Jr.,[5] **Jun. Am. Soc. C. E.**—In all engineering work the procedure adopted for any particular work is determined by the desired accuracy, available working data, purpose of the work, and other considerations. The routing method presented by the authors requires only a small amount of data and therefore may be extremely useful if it meets the other requirements of a particular problem. Some further consideration of the proposed method seems necessary before it can be evaluated properly.

The familiar storage equation, which serves as the basis for nearly all flood routing methods, is an exact formula. There are no simplifying assumptions in the statement "inflow minus outflow equals change in storage." It is not surprising, therefore, that the authors report close agreement between the computed volume of local inflow from the intervening area and the difference in volume of flow at the upstream and downstream stations. Working as they have from zero storage at the beginning of a flood to zero storage at the end of a flood, it would be impossible to have any error in volume other than an arithmetic one.

It is likewise to be expected that the computed hydrograph at the downstream station, obtained by combining the computed local inflow and the observed upstream flow, should check quite closely with the observed hydrograph at the lower station. The volume of flow, of course, should check exactly. Any difference in shape between the computed and observed hydrographs results from the procedure followed. In computing the local inflow, the reach storage was determined by using the sum of the observed inflow and outflow as an index of storage. In the recombination of the hydrographs, the inflow at the upper end and the local inflow are routed separately, using storage values dependent on the particular flow quantities. The process followed is that of dividing the total inflow into a reach into two parts and then adding these parts to get the whole. The error shown in Fig. 4 cannot be explained by a possible error in the Front Royal rating. The changes a flood wave undergoes are dependent on the total storage occupied within a reach. It does not seem rigorous, therefore, to divide the inflow arbitrarily into two parts and route these parts through separate and lesser storage volumes. Because the storage curves used are straight lines, this procedure can be used without introducing serious error.

A mathematically correct solution of the storage equation guarantees a true volumetric answer. The major problem in routing, therefore, is that of obtaining the correct distribution of the stream flow throughout the hydrograph. This requires accurate values of the storage changes during each routing period. True storage volumes are not necessary as long as the changes in storage can be determined correctly. Reviewing the proposed method in the light of known facts about stream flow, it is apparent that certain simplifying assumptions have been made which must of necessity affect the accuracy of the method to a greater or less degree, depending on the characteristics of the particular reach to which it is applied.

---

[5] Asst. Hydrologic Engr., U. S. Weather Bureau, Sacramento, Calif.

Assuming that there is no change in the channel characteristics of a reach during a flood, the storage within the reach is fixed by the water-surface profile. If this profile is a straight line, the stages at the two ends of the reach offer the most accurate measure of the storage within the reach. The authors have used the sum of the discharges at the end points of the reach as their index of storage volumes. This presumes a single-valued relation between stage and discharge, which is not strictly rigorous, although the error is not great for headwater stations such as were used in the examples. The actual water-surface profile in a reach is rarely a straight line during the passage of a flood wave. This fact probably introduces the greatest error in routing. In effect, the authors have used the mean discharge in the reach as their index of storage. Therefore, they are unable to distinguish between the rise and fall of the flood wave; yet it is well known that the shape of the water-surface profile, and therefore the storage volumes, may differ considerably between the rising and falling phases for a given mean discharge. The use of the channel recession to determine storage volumes permits defining the storage curve for falling stages only. The use of stages or discharges at the end points of a reach as separate values by means of a family of curves[6] more effectively defines the slope in a reach than does the mean stage or discharge. Weighting Q and O to give a weighted value of $Q + O$ for the storage index[7] provides a very practical way of adjusting for the effect of rise and fall.

The procedure proposed has not been put to a test effectively by the methods outlined in the paper. The routing of a flood through a reach with large amounts of ungaged local inflow permits only an estimate of the reasonableness of the computed local inflow hydrograph. Test routings of special cases offer an opportunity for a check on the accuracy of a routing method. One such case might be a release from a reservoir without concurrent rainfall. In this case the local inflow will be low and nearly constant, thus permitting a good comparison between observed and computed hydrographs at a downstream station. Similarly, if a river reach within which a large part of the tributary flow is gaged can be found, the local inflow hydrograph can be computed from the upstream and downstream stations only, and this computed hydrograph can then be compared with the total gaged tributary flow adjusted for the ungaged inflow.

The authors suggest that, by prorating the storage volumes and the local inflow on a basis of drainage area, hydrographs for intermediate points of a reach can be computed by routing. Channel storage is a function of channel characteristics and need not show any relation to drainage area. Local inflow volume is controlled by rainfall distrubution and the runoff characteristics of the area under consideration. The shape of the local inflow hydrograph is a function of rainfall distribution with respect to both time and area and to the shape of the contributing area. It would seem advisable to avoid any arbitrary adjustment of storage and flow purely on the basis of drainage area. Contour maps and channel cross sections can be of considerable assistance in the prorating of storage, and the synthetic unit graph[8] can be of much help with the tributary flow.

[6] "Flood Routing," by Edward J. Rutter, Quintin B. Graves, and Franklin F. Snyder, *Transactions*, Am. Soc. C. E., Vol. 104 (1939), p. 275.

[7] Discussion by Ralph W. Powell, *ibid.*, p. 298.

HAROLD C. HICKMAN,[9] ASSOC. M. AM. SOC. C. E.—Flood routing based on accurate and substantial information is at best an intricate and laborious problem. The method described in the paper is particularly interesting in that no cross sections of stream channels, no velocities of flow, and no discharge records on the tributaries are needed. The entire procedure is based upon the storage equation and upon the principle that, for all high stages, there is a straight-line relationship between the volume of storage contained in any reach of the river channel and the sum of the inflow rate at the upper end and the outflow rate at the lower end of that reach. To continue further, it is assumed that at any point downstream the total flow at any instant is comprised of water contributed by many different tributaries, and that the percentage of the total flow occurring at any instant, that is contributed by any single tributary, is constantly changing throughout the flood period.

In analyzing the procedure for the determination of unmeasured inflow, it has been assumed that for any given reach of river channel there is a definite relationship between the volume of channel storage contained therein at any instant and the sum of the simultaneous discharge rates at the two ends of the reach. There is no doubt that this relationship exists, because the discharge is proportional to the river stage at the upper end of the reach, the outflow is proportional to the stage at the lower end, and discharge plus outflow is proportional to the mean stage which, in turn, is dependent on the volume stored in the reach. The relationship between these two quantities varies as a straight line, but, in obtaining the storage in the reach by measuring the area beneath the hydrograph, only a small section of the hydrograph can be used. In other words, this relationship holds good only after the stream has obtained "equilibrium" and is not influenced by overland flow. The entire procedure depends upon the relationship between $(Q + O)$ and the storage in the intervening reach. There is some doubt as to whether a solution should be based on a relationship of this kind.

Assuming for the present that the theory is rational, the next step is to route Q and I through the system to Morgantown. For this purpose, the inflow from the intervening area, I, was ignored, and the storage formula, Eq. 1, was written as in Eq. 3. The quantities on the left-hand side of Eq. 3 are known, giving a quantity which is the summation of $S_1 + O_1$. If Q_1 is added to each side, Eq. 4 results, which was solved by means of the curve in Fig. 2.

The relationship was determined by introducing I into Eq. 1 and therefore cannot be used as a means of solving Eq. 4. In other words, the manner in which the flood peak moves downstream, if the intervening area were not there, is decidedly different from the manner in which the peak will move downstream under the influence of the discharge of the intervening area. On the other hand, if the routing is accomplished by moving the flood peak, as influenced by the discharge of the intervening area, downstream, the problem resolves itself into the simple procedure of segregating the flood peak at Morgantown into its two component parts, depending on the stage-discharge relationship at Fetterman.

---

[8] "Synthetic Unit Graphs," by F. F. Snyder, *Transactions*, Am. Geophysical Union, 1938, p. 447.

[9] Asst. Engr., Flood Control Section, U. S. Engr. Dept., Detroit, Mich.

In comparing the foregoing method of flood routing with other methods, certain facts must be taken into consideration. In the former method, only stream-flow records during a typical flood at a few points on the main stream, or on the tributaries whose flow is to be routed downstream, are necessary. It is universally accepted that when a known volume of water falls on the surface of a drainage area, the rate of resulting river flow at the lower end of the drainage area (point *P*) is influenced by many complex factors. Some of these, such as the consistency and moisture control of the soil, determine how much water will become surface runoff and enter the stream in time to contribute to the flood. Topography, valley storage, and channel storage are all factors in determining the shape of the hydrograph at *P*. After surface runoff has ceased, valley storage governs the flow. When dealing with small homogeneous areas, the evaluation of these factors is needless because the unit hydrograph method evaluates their combined effect as a single entity. With larger and more complex areas there is some question regarding accuracy.

Flood routing divides itself into two distinct problems and combinations of the two: (1) Flood synthesis, which is the determination of the magnitude and time of concentration of flood peaks on the various tributaries; and (2) flood routing, which is the determination of the manner in which these peaks travel and combine themselves with other peaks from other tributaries. Flood routing can be defined further as the procedure by which the hydrograph at any point on a stream is determined from a known hydrograph at some point upstream. As explained, the term "routing" is commonly used to include not only the modification of the flood wave caused by progress downstream, but the further modification caused by any additional flow that enters the river from tributaries or local runoff during this progress.

Factors Affecting Travel.—If a flood hydrograph is divided into elements of equal time, it can be said that certain factors affect the travel of the various elements and alter the shape of the flood wave as it travels downstream.

At the beginning of the flood hydrograph, the first few elements represent a part of the uniform flow of the stream, and they tend to maintain a condition of uniform flow. The elements following, which pass during the rise, have greater slopes and hydraulic radii than the normal river, and, since $V = C\sqrt{RS}$, their velocities are greater than the normal. As the stages rise, part of the discharge is temporarily lost in valley storage. As the flow at the lower end of the reach decreases, the valley storage in the reach will flow out and add to the discharge.

Valley storage in a reach at any time is equal to the inflow minus the outflow, and maximum storage occurs at the point of intersection of the two flow hydrographs. The point of intersection also represents time elapsed, and prior to this time the inflow exceeds the outflow and storage increases; after this, the outflow exceeds the inflow and storage is reduced. The curves intersect at the maximum point on the outflow hydrograph and the areas between the two curves are each equal to the increase of valley storage in the reach. Several factors affect the shape of the flood wave. They may be listed as: Rate of rise, height of rise, slope of channel, stages downstream, downstream channel sections, length of reach, length of crest of hydrograph, and rate of fall.

(1) Rate of Rise.—A rapid rate of rise causes high velocities in the first stages of the flood, which in turn result in the rapid dissipation of these first elements in valley storage, and the consequent retardation of the peak of the flood wave.

(2) Height of Rise.—The higher the stage, the greater the valley storage will be, which in turn causes a flattening of the peak. This causes a greater coefficient of roughness, which reduces velocities.

(3) Slope of Channel.—Greater slopes of the channel will allow more rapid runoff, causing lower stages and less valley storage.

(4) Stages Downstream.—With stages low downstream, a large part of the flood wave goes into valley storage. Increases in downstream stages may cause spreading to the alluvial plain, and thereafter the loss in valley storage will again become large. The propagation and intensity of the peak will be lessened. As the downstream stages are falling at a rate equal to the rate of increase in the rising flood wave, the latter will pass without loss or change due to valley storage, and the stream will tend to maintain a uniform discharge.

(5) Downstream Channel Sections.—If channel sections increase proportionately downstream, loss of valley storage will be greater than if they remain uniform, and the height and rate of propagation of the peak will be correspondingly reduced. If channel sections decrease, the reverse is true.

(6) Length of Reach.—The longer the reach the greater will be the valley storage and the more the peak will be reduced and retarded. These effects vary as a fractional power of the length of reach. Mathematically, in a uniform channel of indefinite length, the rise would be propagated downstream indefinitely, and, since the rate of peak reduction is a finite quantity at the beginning and can never become zero, the curve of successive peaks is concave upward and not a straight line.

(7) Length of Crest of Hydrograph.—The longer the crest, the less is the peak height affected by valley storage.

(8) Rate of Fall.—The more rapid the rate of fall, the more rapidly valley storage will flow out.

The effects that factors (1) to (8) have on a flood wave as it proceeds downstream are individually obvious. In order to route a flood, it is necessary to evaluate the combined effect of all factors. This presents a problem so complex that it defies exact solution by any known method.

A number of empirical methods have been used satisfactorily, but in all of them the stream has been divided into reaches. Since it is desirable to know the stage-discharge relationship at the downstream limit of each reach, the division is generally influenced by the location of gaging stations. Since the shape of the flood wave is constantly being warped by the flow from tributary streams, the accuracy of the computations is inversely proportionate to the length of the reaches. Reaches should be of such length that the simultaneous rates of rise or fall at their extremities are approximately equal and are of the same sense (the latter condition being impossible while the peak is passing through the reach). In the Allegheny and Monongahela rivers, reaches of from 10.6 to 80.7 miles have been used successfully.

All methods of flood routing are based on the solution of the basic equation:

$$I = O + \Delta S \qquad (6)$$

in which, for a given period of time T: I = total inflow; O = total outflow; and ΔS = change in storage. The time T should be no longer than the time of travel of the flood wave through the reach. Various methods, taking into consideration the aforementioned complex factors, have been developed and are generally accepted as giving good results.

Method of Inflow—Storage-Discharge Curves.—In general, the method consists of dividing the stream into reaches and determining the natural valley storage in each reach corresponding to the various discharges at the lower end of the reach. Assuming a straight line function for change of inflow and outflow during a time interval t, Eq. 6 may be written—

$$t\left(\frac{i_1 + i_2}{2}\right) = t\left(\frac{d_1 + d_2}{2}\right) + \Delta S \qquad (7)$$

in which: i_1 = inflow, in cubic feet per second, at initial instant of period; i_2 = inflow in cubic feet per second, at final instant of period; d_1 = discharge, in cubic feet per second, at initial instant of period; d_2 = discharge, in cubic feet per second, at final instant of period; ΔS = increase in storage, in cubic feet per second, during period; and t = length of period, in seconds.

In applying the method, consideration must be given to the flow that enters the reach from tributaries while the flood wave is passing along the reach. For a given value of discharge there will be several different values of valley storage, depending on whether the inflow enters all at one point, or at two points, or at a greater number. If it enters from several different locations, there will be different values, depending on the relative proportions entering at these different locations. Strictly, there are an infinite number of such variations. For practical purposes, however, on any specific reach there may be distinguished a limited number of "types" of floods, depending on which tributary or combination is contributing most of the flow. Separate computations must be made for each different type.

The decision as to how many such general types of floods will be distinguished, of course, must be made by a skilled engineer from a study of the specific reach in question. Among other things, it will depend on the location of the reach. In headwater areas a large percentage of the inflow usually enters from tributaries, whereas lower down the river the flow in the main stream is usually the principal component of the total inflow into the reach.

The storage and discharge curves are obtained by plotting storage and discharge, respectively, against gage height. Daily inflow at the head of the reach and rated tributaries entering the reach are tabulated. From plots of the storm, the rainfall over the area draining directly into the reach can be determined. The local inflow is computed from these data by the distribution-graph method. The daily discharge, gaged at the lower end of the reach, is recorded. The total outflow from any particular flood must equal the total inflow. Ordinarily, they do not check exactly, since there is a greater chance for error in computing the inflow.

With these data, the accumulated storage in the reach can be computed. A time interval of one day is used, and it is assumed that 1 cu ft per sec for one day equals 2 acre-ft (a very close approximation). Eq. 7 can then be written—

$$(i_1 + i_2) - (d_1 + d_2) = \Delta S \qquad (8)$$

in which: i_1 and i_2 are numerically equal to the daily values of inflow in cubic feet per second, but are acre-feet in this equation; d_1 and d_2 are numerically equal to the daily values of outflow in cubic feet per second, but are acre-feet in this equation, and ΔS = increase in storage for the first day, in acre-feet. The curves are then plotted.

This method is used by the Mississippi River Commission to predict flood stages and the time of their occurrence at various points in the main river, resulting from known or predicted conditions of flow in the Mississippi and Ohio rivers at Thebes and Metropolis, Ill., and in the major tributaries downstream.

It is extremely difficult to evaluate all the varied factors that influence flow in a river such as the Mississippi. The computation of the data, although simple in principle, is very difficult in fact. In certain instances, assumptions regarding computations, such as those for evaluating the effect of local and tributary inflow, must be made.

Every such prediction, of course, is based on the assumption that no rains of major proportions will fall after the date on which the prediction is made. If such rains occur, new predictions must be made. For this reason, predictions should be published with caution, since the layman does not always understand their inherent limitations.

Steinberg Method.—A method was developed by I. H. Steinberg, junior engineer, U. S. Engineer Office, St. Paul, Minn., in connection with the 9-ft channel project on the upper Mississippi River.[10]

A group of storage-discharge curves are used for a certain reach of a certain river. They have been obtained by observations of past floods on the reach, and are the same as the inflow storage-discharge curve except that in this case storage is plotted against discharge. There are five different curves, corresponding to five different conditions of backwater resulting from the inflow of a large tributary just below the reach, the volume of that tributary's flow being the parameter of each curve. (This is analogous to the development of several sets of curves in the inflow storage-discharge method, one for each "type" of flood.)

Starting with the fundamental Eq. 7, writing $\Delta S = S_2 - S_1$, and transposing:

$$\frac{t}{2}(i_1 + i_2 - d_1) + S_1 = \frac{t}{2} d_2 + S_2 \qquad (9)$$

---

[10] Civil Engineering, July, 1938, p. 476.

All the knowns are on the left-hand side of Eq. 9, and the two unknowns, d_2 and S_2, are on the right-hand side. Call the left-hand member of the equation the "storage factor," and represent it by M; and let $t = 1$. Then: $M = \frac{d_2}{2} + S_2$ which, transposed, equals:

$$S_2 = M - \frac{d_2}{2} \ldots\ldots (10)$$

If Eq. 10 is plotted, S_2 against d_2, it is a straight line with a slope of -2 and an intercept of the S-axis of M. (Had t been given some other value than 1, the slope, of course, would have been different.) For different values of "M," a family of parallel straight lines may be plotted. Given the foregoing data, and certain basic data, flood routing may be accomplished by simple computations and by interpolation on the set of curves.

Other Methods.—Other methods of flood routing have been used successfully and the Muskingum method is one of them. It is based on the assumption that the ratio of valley storage within a reach to a weighted flow factor determined from both inflow and outflow is constant, and is dependent upon the physical shape of the valley within the reach. This is not theoretically correct, but is a close approximation within a limited range of flood stages.

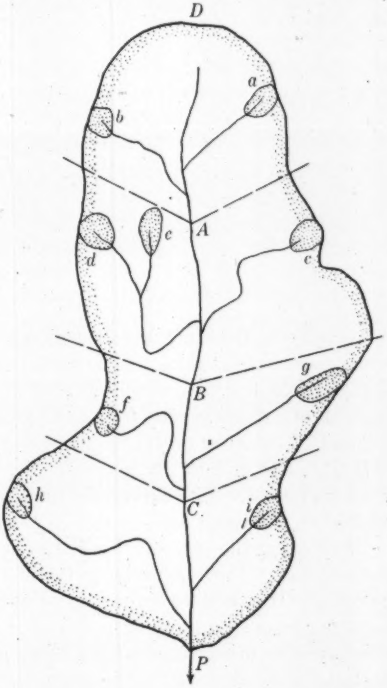

FIG. 5

There is another method that is a combination of the unit hydrograph with flood routing. Where the drainage area is too large to be dealt with by a single unit hydrograph, flood stages are forecast directly from rainfall data. For rivers such as the Connecticut, where the flood wave travels downstream very rapidly, predictions based on rainfall are usually the only ones that can be made far enough in advance to be of much use.

Assume the area PD, Fig. 5, to be drained by the system of streams shown. The method of forecasting stages at P is as follows:

At points A, B, C, and P, unit hydrographs were constructed. These are the hydrographs resulting from 1 in. of runoff over the successive divisions of the total drainage area—that is, the hydrograph at A is for the runoff from area AD, that at B is for the runoff from area BA alone, that at C is for the runoff from area CB alone, etc. The river was considered to be in flood, and these hydrographs were routed separately to *P*. Curves *A′*, *B′*, *C′*, and *P′*, Fig. 6, are the resulting hydrographs at *P*. They show the magnitudes of the elementary flows at *P* resulting from the unit hydrographs at the other points, and also the time lag between the appearance flow at point *A*, *B*, or *C* and of the resultant flow at *P*. The rain is assumed to have started at zero time.

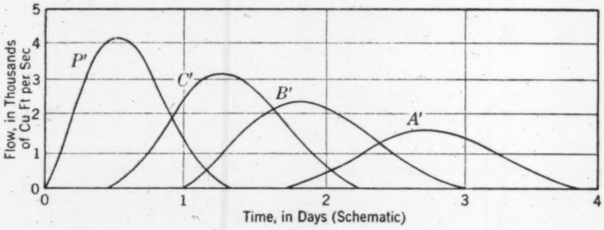

FIG. 6

Gaging stations are installed at points *a*, *b*, *c*, *d*, etc. The small stippled areas are the index areas for the subdivisions. The runoff factors for the index areas are applied to the rainfall on the larger areas in order to determine the number of inches of runoff from these areas. The ordinates of the curves *A′*, *B′*, *C′*, and *P′*, which show the resulting flow at *P* from a runoff of 1 in. over areas *AD*, *BA*, *CB*, and *PC*, respectively, are multiplied by the runoffs in inches as thus computed. The curves are then compounded to obtain the hydrograph at *P* that will result from the given storm.

In routing the individual unit hydrographs at *P*, the river was assumed to be in flood. The operation is therefore accurate only when this condition prevails. It would be erroneous to assume, for example, that the flow at *P* resulting from a 2-in. runoff from area *AD* alone could be found by multiplying the ordinates of curve *A′* by 2. Since no rain fell on areas *PC*, *CB*, and *BA*, the stages of the stream in those areas would be normal when the flood waters from upstream arrived, and much of the flood flow would be taken up in valley storage. The peak at *P* would therefore occur later than curve *A′* indicated, and would be lower than the value obtained by multiplying the maximum ordinate of *A′* by 2.

Conclusions.—It can be noted from the foregoing that flood routing with all of its complex factors cannot be considered in the light of the information from one or two flood hydrographs. When seven or eight factors, each having considerable individual effect on the size and shape of the flood hydrograph, join together in different combinations, depending upon the assimilation of predetermined conditions, the resulting effect on the flood hydrograph may be unpredictable unless all of the information that can possibly be collected is analyzed and given consideration in a manner suitable to its importance to the problem.

It is believed that the method described by Messrs. Wisler and Brater is unique and should be tested under varying conditions. It may be that this method eliminates most of the tedious work connected with the routing of floods in a large and intricate drainage system. However, the most serious objection to the method is that it is based on the assumption that routing within a basin may depend on what has happened during one flood. Can it be said that a major storm, and the resulting flood, will proceed according to the same plan every time? Unless it is true that all of the factors affect all floods on a particular stream in the same manner and to the same degree during every storm, there is no reason why each flood will not be different from its predecessor even though the storm producing it begins under identical conditions. In other words, every storm should be studied separately, so that each factor affecting the flood can be isolated and compared if possible.

Any method, in which the contributing factors can be used in different combinations to determine the resulting effect, appears to be more rational than a method that proposes to assume that all floods proceed according to the same plan under all combinations of meteorological, channel, and basin conditions.

ROBERT B. HORONJEFF,[11] AND HERBERT G. CROWLE,[12] JUNIORS, AM. SOC. C. E.—The flood-routing technique presented in this paper may prove to be of considerable value, provided the full significance of the various operations is understood by those who use the method.

The writers are in complete agreement with the basic equations presented, but they believe that the authors have not given sufficient explanation of the following features:

(1) The expression "storage in the intervening reach" includes the storage in all channels tributary to the reach as well as the storage in the main channel. This fact must be kept in mind in any attempt to visualize the proportionality of "storage in the intervening reach" and the "sum of the inflow rate at the upper end and the outflow rate at the lower end of that reach."

(2) Referring to Fig. 1, the agreement of the composite of the routed hydrographs with the gaged hydrograph O at the lower end of the reach is merely a check on the arithmetical operations performed in deriving the hydrograph marked I, and in routing I and Q through the reach with the straight-line relation between S and $(Q + O)$ shown in Fig. 2. The agreement is in no sense a check on the accuracy of the gaging at the lower station, or the correctness of the lines in Fig. 2.

As proof of the foregoing statement, the writers present the set of hydrographs for the Pajaro River, California, in Fig. 7, corresponding to Fig. 1, and the inflow-outflow-storage lines in Fig. 8, corresponding to Fig. 2. A characteristic flood is routed from Sargent to Chittenden, Calif., discharge records being available at both of these places. The hydrographs marked I, I', and Q' were obtained by the methods outlined in the paper, using the "S versus $(Q + O)$" and "$S + (Q + O)$ versus $(Q + O)$" curves derived from the recession curves of hydrographs Q and O. The sum of the hydrographs I' and Q' was so close to the hydrograph O as to be indistinguishable. In Fig. 8, a second "S versus $(Q + O)$" curve was then drawn at random, with the corresponding "$S + (Q + O)$ versus $(Q + O)$" curve, and the hydrographs I'', I''', and Q''' derived with these new lines. The curve I'' represents the fictitious hydrograph of inflow from the intervening reach, I''' that hydrograph routed through the reach, and Q''' the fictitious routed hydrograph of Q. The sum of I''' and Q''' agrees exactly with the original gaged hydrograph O, proving that the agreement depends only upon the use of a straight line—any straight line—for the routing operation. This is perhaps the most important criticism of the paper—namely, that the agreement of the composite of the routed hydrographs with the gaged hydrograph does not prove the accuracy of the results in a physical sense.

---

[12] Asst. Civ. Engr., U. S. Engr. Dept., San Francisco, Calif.

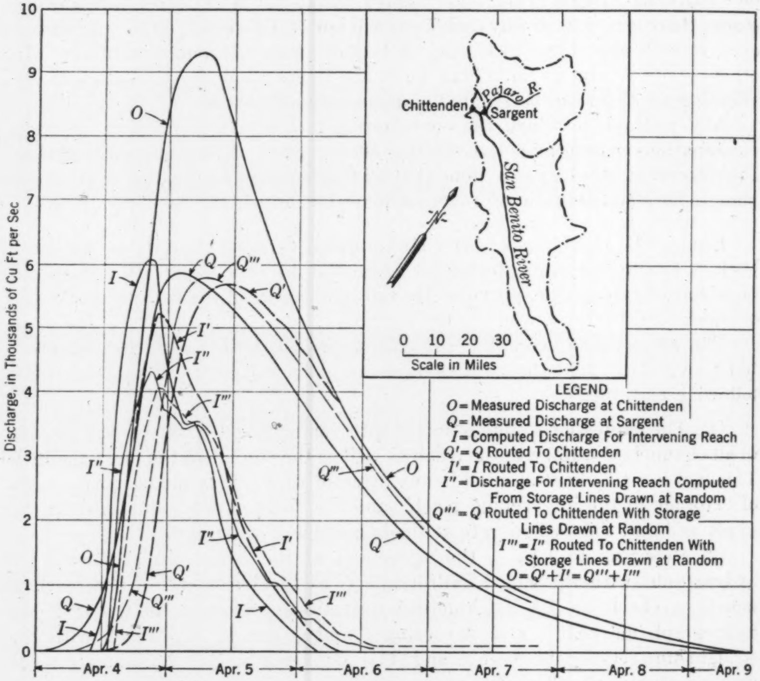

FIG. 7.—HYDROGRAPHS OF SURFACE RUNOFF, WATERSHED OF THE PAJARO RIVER, CALIFORNIA

(3) The authors did not indicate whether the storage curve derived from one flood would plot in very nearly the same position as those obtained from other floods. The writers found, in the case of the Pajaro River, that "S versus $(Q + O)$" curves, which were derived from different floods, plotted in different positions and with appreciably different slopes, indicating that there is no one curve that is characteristic of a particular reach during all floods.

(4) Base flow may be included in the routing operation, thus eliminating the necessity of adding this value to obtain the complete routed hydrograph at the lower end of the reach.

(5) Finally, the writers wish to emphasize that the authors so far have presented no evidence to prove that their method of routing gives the correct reduction in peak discharge to be expected from a reservoir constructed on a

tributary. In fact, it appears to the writers that the nature of the method precludes the possibility of a check upon the physical results. Any errors in gaging or in deriving the "S versus $(Q + O)$" curve are automatically included in the derivation of the hydrograph of computed discharge I for the intervening reach.

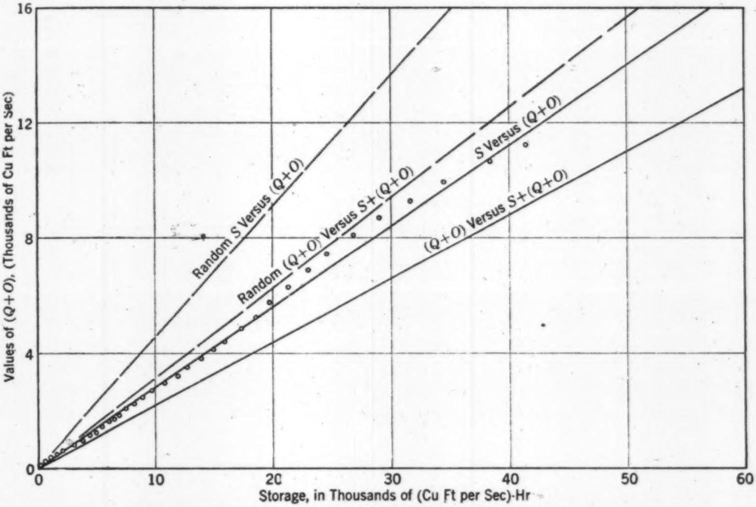

FIG. 8.—RELATION BETWEEN $(Q + O)$ AND THE STORAGE IN THE INTERVENING REACH, PAJARO RIVER, CALIFORNIA

L. K. SHERMAN,[13] M. AM. SOC. C. E.—The writer has tested the authors' flood routing method by utilizing an example published in 1940.[14] The gaged stations, reported by the authors, at Morgantown and Fetterman correspond with the two points at the ends of the lower (6-ft base) reach of the main channel, shown in Fig. 9.[15] The authors' hydrograph O corresponds with "(b) Heavy Rain," in Fig. 10. The hydrographs, corresponding to the authors' Q and routed Q_1, are plotted as curves d and e in Fig. 10.

The relation of cubic feet per second at the outlet station, to the valley storage, was determined from recession curves of the hydrographs O, Q, and also from the small hydrograph in Fig. 10 marked "(a) Light Rain." The points were platted on logarithmic paper similar to the diagram given by Robert Horton,[3] M. Am. Soc. C. E. All of the points below the contraflexure on the recession curves of the hydrographs fell on a straight line, except low values of cubic feet per second. In this example, all surface runoff ceased at the time 8,400 sec, as shown by the hydrograph of overland flow,[16] Fig. 11, for one unit of area. This time checks with the points of contraflexure. The total overland flow from the "heavy rain" on one unit strip of 1,100 ft is 71 cu ft. The total volumes of runoff, for checking purposes, are: Hydrograph Q or Q_1 is 44,000 × 71 cu ft. The volume I for the reach is 16,000 × 71, and the volume of hydrograph O is 60,000 × 71.

Fig. 9.—The Drainage Area

The writer platted a diagram of $(Q + O)$ versus storage, with time units of 250 sec, corresponding with Fig. 2. The fifteen points all fell on, or close to, a straight line through the two points $(Q + O) = 150$ cu ft per sec versus $S = 392$ cu ft per sec (250 sec) and $(Q + O) = 1,353$ cu ft per sec versus $S = 3,260$ cu ft per sec (250 sec). The line $(Q + O)$ versus $S + (Q + O)$ was also platted.

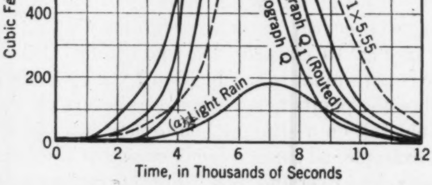

Fig. 10.—Main Channel Hydrographs for Both Light Rain and Heavy Rain

The writer's routed hydrograph Q_1 was derived with this diagram and with Eq. 4. The tails of his recession curves Q_1 and O did not coincide as do the similar curves of the authors. The writer knows of no reason why they should coincide. Even with equal durations of rainfall, the recession curve of the hydrograph with the lesser peak and volume will fall inside the larger. As an extreme case, note the two hydrographs in Fig. 10.

Conclusions.—(1) The authors have presented a reliable method that will be useful in many problems of flood routing.

(2) In selecting recession curves for the relation between discharge rate and storage, avoid, if possible, hydrographs affected by rainfall or surface runoff during the recession period.

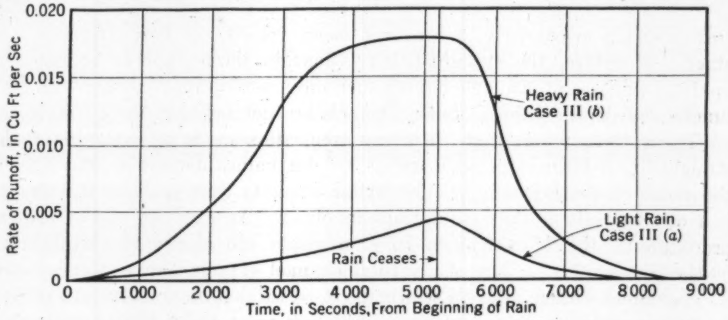

FIG. 11.—OVERLAND FLOW FROM A 1-FT STRIP 1,100 FT LONG, WITH DETENTION STORAGE

(3) The straight-line relation for $(Q + O)$ versus storage exists for a longer period than the similar line for discharge and storage.

A supported hydrograph (that is, one receiving increments of water as it moves downstream) may be routed by Seddon's wave velocity if the channel areas are known. The routed hydrograph will check with the storage equation at any time. A hydrograph routed by stream velocity will not check with the storage equation. The total volumes will agree, but the forms of the hydrographs will not agree.

An attempt was made by the writer[14] to compare the known volume of the reach with the volume derived by the difference of total hydrograph volumes, but it was not too successful.

It would appear that, on natural streams, more reliable values of storage could be derived by the authors' method than by cross-section surveys.

ALFRED L. BROSIO,[17] JUN. AM. SOC. C. E.—The method of flood routing that the authors have presented involves assumptions that need further explanation. The comments which this writer wishes to present will be separated into two parts—I. Discussion of the assumption of a straight-line flow-storage relation; and II. Analysis of the assumption: Storage = function (inflow + outflow).

I. Assumption of Straight-Line Flow-Storage Relation.—In the "Conclusion," the authors have stated their belief that "except possibly under unusual channel conditions, the curve of relationship between channel storage in the intervening reach and the sum of the discharges at the two ends of the reach is a straight line for the normal and high stages of the river." Although such a relationship is sometimes found to exist in natural channels, it is not believed to represent the "usual" channel conditions. This can be shown as follows: Let S = volume of channel storage in second-foot-hours; Q_u = uniform rate of flow, through entire reach, in cubic feet per second. A straight-line relationship between S and (inflow + outflow) implies that $\frac{S}{Q_u}$ = constant; but a constant value of $\frac{S}{Q_u}$, which is in units of time, represents a constant time of travel, and, consequently, a constant mean velocity of flow irrespective of stage. Therefore, the straight-line relationship should not be assumed to apply in the case of channels having such cross section that mean velocity is a function of depth of flow. Such channels are not believed to be "unusual."

---

[17] Engr., Missouri Val. Bridge & Iron Co., Evansville, Ind.

The authors report that "in every application made to date (1941), this straight-line relationship holds true * * * for values derived to the right of the point of contraflexure." The writer suggests that perhaps this finding is a direct result of the assumptions involved. An analysis of the authors' procedure in the Monongahela River example will clarify the implications of the last sentence. Let: S_m = total channel storage above Morgantown; S_f = channel storage above Fetterman; S_a = total storage in the channels of the "intervening area"; S = storage in the Fetterman-to-Morgantown channel; S_i = storage in the channels of the "intervening area," exclusive of S (the intervening area comprises 50% of the total area above Morgantown, and many miles of channel are included therein in addition to the Fetterman-to-Morgantown channel); O = Morgantown flow; Q = Fetterman flow; and I = flow from the "intervening area."

The example is somewhat complicated because of rain that fell from March 26 to 28, during the period of recession which the authors chose for their study. However, the writer does not contest the statement of the authors to the effect that, had not this additional rain fallen, values of $(S_m - S_f)$ computed from the respective hydrographs subsequent to the point of contraflexure would have plotted against $(Q + O)$ as a straight line; but $S_m - S_f = S_a$; and $S_a = S + S_i$. Therefore, by adopting a curve conforming with plotted points of $(S_m - S_f)$ versus $(Q + O)$, to represent S versus $(Q + O)$, the authors in effect assumed S_i, and consequently I, to equal zero. Going on to the next step in the authors' procedure, the hydrograph of I was developed, using the adopted flow-storage relation, and found to equal zero during the periods in which it had been so assumed by implication; but it is obvious that had any other assumption been implied with regard to the value of I, the results would have confirmed such assumption quite as well. For example, the writer has made a test in which a curve of S versus $(Q + O)$ was adopted conforming with the authors' curve up to $(Q + O)$ = 10,000 cu ft per sec and having a "concave-upward" shape thereafter. The assumption implied by such a curve is that S_i did not deplete itself until $(Q + O)$ receded to a value of 10,000 cu ft per sec, shortly before noon on March 29. The hydrograph of I, developed as required by the authors' equations and using the concave curve, confirms the implied assumption of the writer, although it is understood that such assumption is probably no better than the one implied by the authors. The detailed calculations and results of this test are not presented herewith, but a similar test may be made in a short time by any one desiring to verify the foregoing statements.

It appears, therefore, that the method used by the authors to compute channel storage may be somewhat unreliable. Unfortunately, the writer is not at all familiar with the streams studied by the authors, nor with the quantity and quality of meteorological and hydrological data available. However, assuming the existence of a very minimum of such data, the writer would recommend the following general procedure to obtain the volume of storage in a channel such as the one from Fetterman to Morgantown:

1. Choose for analysis that flood, for which both Fetterman and Morgantown flows are known, which offers the best combination of the following: (*a*) Precipitation data in, or near, the "intervening area"; and (*b*) a minimum percentage of total runoff above Morgantown originating from the "intervening area."

2. Using the method devised by Otto H. Meyer,[18] Assoc. M. Am. Soc. C. E., for determining hydrographs for areas lacking in runoff records, the hydrograph of flow from the intervening area during the flood chosen for analysis may be estimated as to shape, total volume being known from the difference "Morgantown minus Fetterman." Should the basic data used in conjunction with Mr. Meyer's method be very poor, the choice of a flood having the quality of Item 1(*b*) will be of definite advantage.

3. Storage in the channel Fetterman-to-Morgantown may then be computed at any instant, knowing total inflow, as well as outflow, during any interval of time. This channel storage may then be used in further studies, to determine its relation to other variables. Since Mr. Meyer's method makes available not only the hydrograph *I* subsequent to the point of contraflexure, but the entire flood hydrograph, larger values of channel storage may be computed than from a method limited to analysis of recessions.

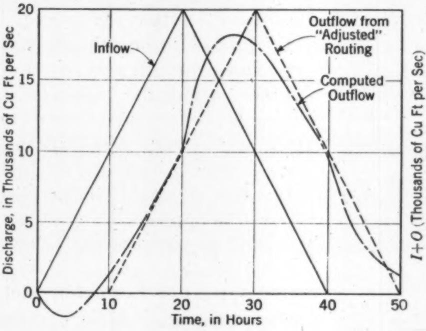

FIG. 12

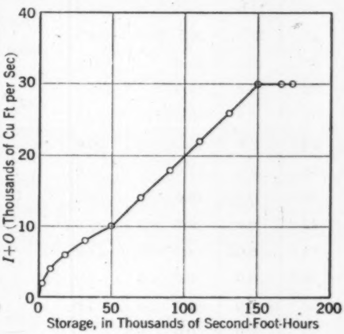

FIG. 13

Of course, it is not to be understood that the method outlined herein to compute channel storage is the only acceptable one. With more basic data the selection of methods becomes correspondingly greater. It is possible that had the authors determined channel storage in the various reaches by a more reliable method, the correlations of S versus (inflow + outflow) might not have yielded straight lines.

---

[18] "Analysis of Run-Off Characteristics," by Otto H. Meyer, *Transactions*, Am. Soc. C. E., Vol. 105 (1940), pp. 83–100.

II. Storage as a Function of (Inflow + Outflow).—The statement (see heading "Determination of Unmeasured Inflow") that "there is a definite relationship between the volume of channel storage * * * at any instant and the sum of the simultaneous discharge rates at the two ends of the reach" sounds very logical at first thought. However, it is an assumption, the weaknesses of which should be fully understood.

Let the hydrograph represented by the full line of Fig. 12 be the total flow into a reach of channel, entering entirely at the upper end of the reach. Also, assume that the relationship between storage and uniform flow is a straight line, having a value of inverse slope equal to 10 $\frac{\text{second-foot-hours}}{\text{second-foot}}$, or 10 hr. If the inflow is routed through the reach according to the method presented by the authors, using 2-hr periods, the outflow hydrograph indicated in Fig. 12 by the dash-dot symbol is the result. There are three apparent inconsistencies in that hydrograph: (1) Outflow is negative during the first 8 hr; (2) rate of rise of outflow suddenly increases at Hour 20, when inflow begins to fall; and (3) rate of fall of outflow suddenly increases at Hour 40, when it would be expected to do the opposite.

The writer does not believe that a detailed explanation is required, relating to the foregoing inconsistencies. It is obvious that the assumption storage = function (inflow + outflow) assumes a uniformly varying flow between the two ends of the reach and that such a condition does not exist during the three periods of discrepancy. The same types of inconsistencies occurred in the examples presented by the

authors. Some good illustrations may be found in the routing of Q into Q', in Fig. 1. The writer believes that the authors must also have obtained negative values of flow, not shown in the hydrographs of Figs. 1 and 4.

It is possible to make certain "running adjustments," during the process of routing the triangular hydrograph of Fig. 12, to eliminate the effect of the discrepancies already mentioned. Table 2 presents the calculations by means of which this is accomplished. The general procedure consists of routing by the authors' method except that, for each impossible value of outflow which is obtained, the nearest possible value is substituted. The following nomenclature is used: I = total flow into reach, entering entirely at upper end, 1,000 cu ft per sec; O = outflow in 1,000 cu ft per sec; and S = channel storage in 1,000 sec-ft-hr. In Table 2, the fifth column contains progressive values of

$$S_0 + I_0 + 2\,I_1 - O_0 = S_1 + I_1 + O_1 \qquad (11)$$

which corresponds to Eq. 4 of the paper. Assuming that S = function $(I + O)$, the uniform-flow-versus-storage relation which has been assumed for the reach gives

$$S = 5\,(I + O) \qquad (12)$$

It follows that the relation required for obtaining the sixth column of Table 2 by the authors' method is

$$I + O = \tfrac{1}{6}\,(S + I + O) \qquad (13)$$

When the values of storage in Table 2 are plotted against simultaneous values of $(I + O)$, the result shown in Fig. 13 is obtained. It seems as if the effect of the writer's "adjustments" may have been in the direction of "correcting" the relation between storage and $(I + O)$ for the fact that the variation of flow between inlet and outlet is concave upward from Hour 0 to Hour 10, and from Hour 40 to Hour 50, while being concave downward from Hour 20 to Hour 30. The resulting hydrograph of outflow is shown in Fig. 12 by the short dashes. It is seen to be a perfect image of the inflow hydrograph, with a time lag of 10 hr.

It is generally agreed that if, at all sections of a reach, discharge were entirely dependent on stage, the outflow and inflow hydrographs would be identical in shape. Although this condition is sometimes approached in natural river reaches, it should not be assumed to represent the general case. Since the assumption that storage is a function of average flow in the reach obviously implies such a condition, a method of flood-routing based on that assumption is not adaptable to general application.

Several routing methods used in present practice take care of the individualities of any given reach by means of factors embodied in the procedure. These factors, however, are generally unreliable unless they are evaluated from analysis of at least one flood, for which hydrographs of total inflow and outflow are either known or obtainable by estimation. The writer believes, however, that a practical method of flood routing, the required factors in which can be determined directly from the measurable physical properties of the reach, can be developed.

In the meantime, it is suggested that a more satisfactory solution of the authors' problems could perhaps be effected by the following procedure:

1. Using the procedure outlined in part I of this discussion, obtain the hydrograph of channel storage, for the flood chosen for study.
2. Plotting values of outflow against simultaneous values of storage should give a loop showing a larger volume of storage for a given discharge during rising stages than during falling stages. By plotting values of storage against later values of outflow, a number of trials will indicate what time interval between storage and outflow effects the best closure of the loop into a curve.
3. The inflow hydrograph could then be routed according to a method presented by Otto H. Meyer,[19] using a "storage lag" as nearly as possible equal to the time interval which effected best loop closure. The result should be a more or less satisfactory outflow hydrograph, depending on the reliability of the data used in previous steps. Incidentally, the process of obtaining the storage-outflow relation and storage lag is described in more detail by Mr. Meyer in the publication cited.[19]
4. Using the same routing procedure, outflow may then be computed for any recorded or assumed total inflow, or by reversing the routing procedure, total inflow may be computed for any recorded or assumed outflow.

W. B. LANGBEIN,[20] ASSOC. M. AM. SOC. C. E.—A reading of this paper seems to give the impression that the objectives of flood routing as set forth in the first paragraph are not being realized at present. In their presentation the authors seem to overlook the fact that floods are being routed daily and expeditiously by empirical methods as described in the following references which are evidently as simple as those they proposed:

(13) "Storage and the Unit Hydrograph," by C. O. Clark, Jun. Am. Soc. C. E., U. S. Engr. Office, Norfolk, Va., 1940 (unpublished).

The authors undertake to compute a hydrograph of inflow from the unmeasured area and refer (paragraphs preceding "Routing Q and I Through to Morgantown") to a comparison between two methods of computing the volume of inflow. It appears to the writer that the two methods are one; any difference should be ascribed to arithmetic discrepancies.

For example, in method 1, $\sum$ outflow at Morgantown $-$ $\sum$ flow at Fetterman = total intervening inflow, whereas in method 2,

$$I = \frac{O_2 + O_1}{2} - \frac{Q_2 + Q_1}{2} + \frac{S_1 - S_2}{\Delta t} \dots\dots\dots\dots (14)$$

in which Δt is time intervening between events indicated by subscripts 1 and 2.

From the beginning of the hydrograph to its end, storage fluctuates from zero back to zero; hence,

$$\sum I = \sum \frac{O_2 + O_1}{2} - \sum \frac{Q_2 + Q_1}{2} \dots\dots\dots\dots (15)$$

as before. Hydrographs of channel inflow from intervening, partial, and total basin areas were computed by the U. S. Geological Survey by Eqs. 14 and 15 as a part of its analysis of the Ohio River flood of January, 1937 (1).[21]

The authors state (see "Synopsis") that

> "The entire procedure is based upon the storage equation and upon the principal that, for all high stages, there is a straight-line relationship between the volume of storage contained in any reach of river channel and the sum of the inflow rate at the upper end and the outflow rate at the lower end of that reach. Except perhaps for unusual channel conditions, this relationship holds true."

This statement is not generally supported by studies of others. G. T. McCarthy, Assoc. M. Am. Soc. C. E. (6), showed that, in the general case, unless proper weights were assigned to inflow and outflow, the discharge-storage relation was a loop. The special case of the authors, of equal weights to outflow and inflow, has been shown by the writer (5) and others (13) to be comparable to simple translation.

The straight-line relationship between weighted discharge and storage is approximated by many reaches. It is a convenience but not a necessary corollary to general flood-routing technique, and is not a proof of the authors' general statement that overland flow ceases and channel storage-drainage begins at the time of the point of contraflexure on the recession side of the hydrograph. It may be true for a minor tributary but certainly does not hold true for larger basins. For example, in Fig. 1 the point of contraflexure occurs later on the Morgantown hydrograph than on the one at Fetterman; evidently, this is simple hydraulic lag. The time of contraflexure was even later at Charleroi, Pa., and, as one proceeds downstream, even the peak may be considered as drainage from upstream areas from which overland flow had long since terminated.

---

[21] Numerals in parentheses, thus: (1), refer to the foregoing references to current literature on "Channel Storage and Flood Routing."

The writer has used the method of computing storage relations from recession curves (5). From his experience he would be very much surprised if points prior to the point of contraflexure did not plot to the right of the curve as in Fig. 2, and he cannot accept this as proof that this is the point of termination of overland flow.

The method of verification adopted by the authors (applying empirical formulas directly to the material used to derive them) may be deficient to the extent that the data used in the derivation of the technique may have sampled only a limited number of experiences. A later flood representing an entirely different combination of events may prove such empirical methods to be unreliable. Present flood-routing technique has many shortcomings, and there is a great need for the application of some of the more general laws of fluid motion to the problem to replace present empiricisms. It seems probable that the authors did not take full advantage of the considerable amount of published material relating to the technique of flood routing.

FRED E. TATUM,[22] JUN. AM. SOC. C. E.—The method advanced by the authors for obtaining their storage curves saves considerable time. The curve thus obtained represents the true storage for that particular storm rather than the average curve as computed by other methods.

The true recession curve is an exponential curve[23,24] and the recession factor can be designated by "K." The recession factor "K," of both the upper and lower gaging stations, must be equal for the S versus $(Q + O)$-curve to be a straight line. In the case of unequal recession factors, S versus $(Q + O)$ will plot as a curved line.

Since the recession curves are exponential and equal, the S versus $(Q + O)$-curve should be a straight line starting at the origin and drawn parallel to the curve used by the authors. The curved line obtained at lower stages by the authors is apparently due to the fact that the point at which surface runoff appeared to end was sooner than the actual ending time.

This routing method gives good results when the two gages are reasonably close together, but if the reaches are too long for the period of time required for routing, the results cannot be depended upon. One of the requirements in routing is that the reach should be of such length that the time of travel through the reach is about the same as the length of the period used in routing.

---

[22] Junior Engr., U. S. Engrs., Rock Island, Ill.

[23] "Relation Between Rainfall and Run-Off from Small Urban Areas," by W. W. Horner and F. L. Flynt, *Transactions*, Am. Soc. C. E., Vol. 101 (1936), p. 140.

[24] "The Mathematical Synthesis of the Flood Hydrograph," by R. T. Zoch, *Transactions*, Am. Geophysical Union, 1939, p. 207.

It seems that the authors went to considerable trouble in computing the local inflow and then routing it down to the gage, when it is readily obtainable by an easier method. The hydrograph of local inflow, of necessity, would be at the lower gaging station, and therefore would not need to be routed. The local inflow hydrograph can then be obtained by subtracting the routed flows of the upper gaging station from the flows of the lower gaging station. The difference will be the hydrograph for the local inflow.

H. C. WOSTER,[25] ASSOC. M. AM. SOC. C. E.—The method of flood routing developed by the authors is felt to be a distinct contribution to the methodology of delineating flood and damage source areas. The method is particularly adapted to use in the flood-control preliminary examinations and surveys of the Department of Agriculture, in the prosecution of which it is usually impracticable and economically impossible to obtain the channel cross sections and other hydraulic data requisite to the more exact methods of flood routing.

The authors' method has been used during and since its development in the flood-control preliminary examinations conducted by the Appalachian Forest Experiment Station, at Asheville, N. C., and, since May, 1941, under the supervision of the Regional Office, Bureau of Agricultural Economics, at Atlanta, Ga. The method was used first as a means of defining the principal sources of flow contributing to downstream damages, but in studies made since May, 1941, routings made by this method have been used as a basis for allocating actual flood damages at critical downstream points to the respective tributary areas. The allocation of damages to source areas in turn becomes one of the bases for determining the critical areas on which a land-use improvement program can be expected to contribute to flood reduction. The flow routing is used also for approximating the contribution of each area to the anticipated reduction.

This discussion is intended to present some of the difficulties encountered in the application of the method, in the hope that they may be considered by the authors in any further development and refinement of the method. It is regretted that solutions of the difficulties cannot be offered in this discussion.

The authors state that their selection of gaging stations for illustration was based partly on the excellent discharge records available. It is evident from the presentation that very good results have been obtained with these records. In the studies made by the writer it has been necessary to use the available discharge records for the watersheds studied, many of which are less reliable than those used by the authors because of lack of definition of stage-discharge relationships for high stages or because of complications due to backwater, slight regulation, or other causes. Gaging station records affected by pronounced stream regulation have not been used. The results obtained by using the regular run of discharge records are less fortunate than those encountered by the authors. It has been found necessary in most cases to adjust the routed hydrographs of Q and I after completion of the procedure because when they are combined they do not check, even closely, the actual hydrograph. In some cases the adjustments have been rather large, necessitating the exercise of personal judgment and hence detracting from the usefulness of the routing method as an exact procedure.

---

[25] Takoma Park, Md.

In most cases where adjustment of the routed hydrographs has been made, it has been found necessary to reduce the peak of the routed hydrograph of Q and move it ahead in point of time. This appears to indicate that the relationship of $(Q + O)$ to channel storage does not yield sufficiently large storage values. This has been found to be particularly true in cases where the distance between gaging stations is long. One reason for this may be that the relationship between $(Q + O)$ and channel storage was developed from the recession side of the hydrograph and does not take account of the fact that for a given stage the channel storage is greater on the rising than on the recession side of the hydrograph. Consequently, the application of the authors' channel storage relationship reduces the peak discharge in transit between stations less than actually occurs. Also, the actual time of transit of the flood wave is greater than that obtained by this method.

It has been found that, in computing outflow from the inflow hydrograph of Q, negative values of outflow are often obtained for a number of periods at the beginning of the outflow hydrograph. Since the total volume of Q', including the negative values, equals the original volume of Q, then, if the negative values of Q' are called zero, the total outflow becomes greater than the original volume. This is believed to be due to errors in the slope of the storage curve near its lower end and doubtless could be corrected by adjusting the slope of the storage curve by trial and error. It has been found to be quicker and more convenient, however, to adjust the hydrograph of Q' directly to the original volume.

C. O. WISLER,[26] M. AM. SOC. C. E., AND E. F. BRATER,[27] JUN. AM. SOC. C. E.—The interest shown in this paper was very gratifying to the writers. Many of the discussions showed the results of long hours of study and preparation. To all those who contributed constructive criticisms, the writers wish to express their very sincere appreciation.

Several pertinent questions were raised that are of fundamental importance and vitally affect the validity of this method of flood routing. In seeking the answers to these questions, one must keep in mind that no exact method of flood routing has ever been devised. All methods are based on certain assumptions. Naturally, the accuracy of the results depends upon the extent to which the assumptions are in error. Any theoretical proof that a method is wrong is utterly meaningless unless it can be shown that the resulting error is of a magnitude so great as to render the results of little or no value. The writers recognize the assumptions involved in their flood-routing procedure and have attempted to evaluate the resulting errors so as to determine whether or not their magnitude is so great as to seriously impair the value of the procedure.

One of the assumptions upon which this method of flood routing is based is that the relationship between $(Q + O)$ and S is substantially the same during rising and falling stages. In many cases, especially in the upper reaches of a stream, this is true, but there are instances where this assumption may not seem justifiable. The error in such cases is due to the fact that a given amount of channel storage corresponds to a larger discharge when it occurs on the rising side of a graph than when it occurs on the falling side. In such cases the curve relating $(Q + O)$ to S becomes a loop for which, if $(Q + O)$ is plotted on the vertical axis, the upper part applies to the rising side of the graph and the lower part to the falling side. Each routing requires its own particular loop, the location of which must be fixed step by step as the routing proceeds. A method for accomplishing this is illustrated by an example. For this purpose the reach of the Ohio River from Pittsburgh, Pa., to Wheeling, W. Va., was selected because it is known that for any given stage at Wheeling there is an unusually great variation in discharge between the rising and falling stages. In order to simplify the example it is assumed that no correction is required at the upper station.

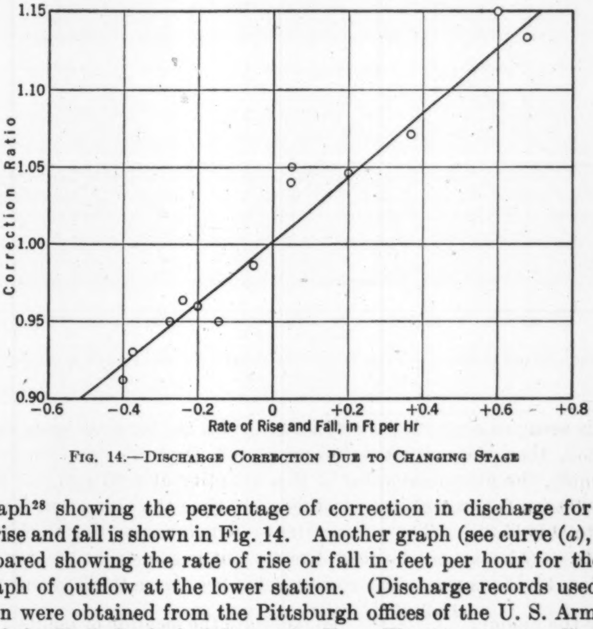

FIG. 14.—DISCHARGE CORRECTION DUE TO CHANGING STAGE

A graph[28] showing the percentage of correction in discharge for various rates of rise and fall is shown in Fig. 14. Another graph (see curve (*a*), Fig. 15) was prepared showing the rate of rise or fall in feet per hour for the actual hydrograph of outflow at the lower station. (Discharge records used in this discussion were obtained from the Pittsburgh offices of the U. S. Army Engineers and the U. S. Geological Survey.) From Fig. 14, corresponding correction factors were read and plotted as curve (*b*), Fig. 15. From this graph, the correction factor at any time during the course of the flood may be determined.

The curve relating $(Q + O)$ to S is obtained as in the original example except that values of O must be corrected before being plotted. For example, at noon of March 21, O is 111,000 cu ft per sec, Q is 17,000 cu ft per sec, and the storage is 1,778,000 (cu ft per sec)-hr. The rate of fall at this time was such that a correction factor of 8.0% must be applied to O. Since 8% of 111,000 is 9,000, the foregoing value of storage is plotted against 111,000 + 17,000 + 9,000, or 137,000 (cu ft per sec)-hr. When such values are plotted, a straight line is obtained that shows the relationship between S and $(Q + O)$ for stable river conditions. The auxiliary curve relating $(Q + O)$ to $S + 3\,(Q + O)$ is also plotted (see Fig. 16).

---

[28] Data obtained from "River Discharge," by J. C. Hoyt and N. C. Grover, 3d Ed., John Wiley & Sons, Inc., New York, N. Y., 1914.

The routing is then determined by successive solutions of the following equation:

$$S_0 + 3\,Q_0 + 6\,Q_1 - 3\,O_0 = S_1 + 3\,(Q_1 + O_1) \qquad (16)$$

Eq. 16 corresponds to Eq. 4, the difference in coefficients being due to the fact that 6-hr intervals are used here instead of 2-hr intervals.

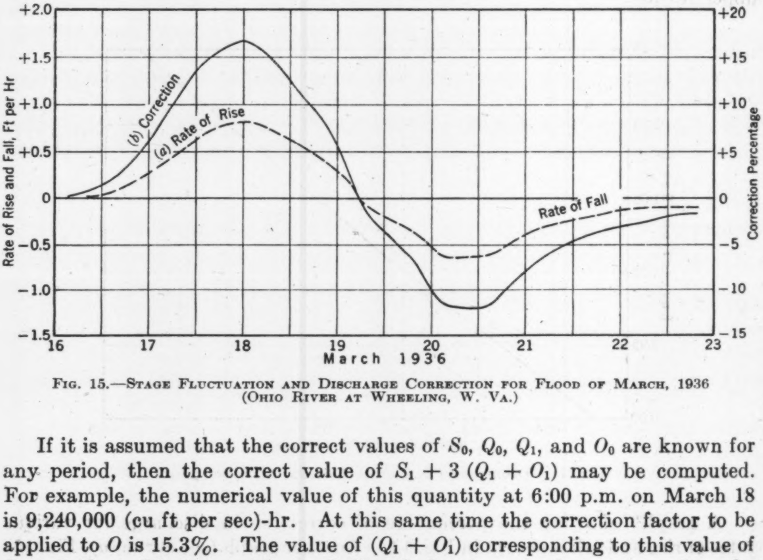

FIG. 15.—STAGE FLUCTUATION AND DISCHARGE CORRECTION FOR FLOOD OF MARCH, 1936 (OHIO RIVER AT WHEELING, W. VA.)

If it is assumed that the correct values of S_0, Q_0, Q_1, and O_0 are known for any period, then the correct value of $S_1 + 3\,(Q_1 + O_1)$ may be computed. For example, the numerical value of this quantity at 6:00 p.m. on March 18 is 9,240,000 (cu ft per sec)-hr. At this same time the correction factor to be applied to O is 15.3%. The value of $(Q_1 + O_1)$ corresponding to this value of $S_1 + 3\,(Q_1 + O_1)$ may not be read directly but is somewhat greater than the value given by the curve. The correct value lies above the S versus $(Q + O)$-curve by the amount $\frac{15.3}{100} \times O$. To facilitate the location of points at various distances above or below the S versus $(Q + O)$-curve, a series of straight parallel lines at intervals of 10,000 cu ft per sec above and below the line is drawn. Corresponding parallel lines are drawn for the auxiliary curve.

If, as a first trial, O is assumed to be about 200,000 cu ft per sec, the correction will be + 30,000 cu ft per sec. A point on the + 30,000 correction line of the auxiliary curve is located that has an abscissa of 9,240,000 (cu ft per sec)-hr. The corresponding value of $(Q + O)$ is seen to be 602,000 cu ft

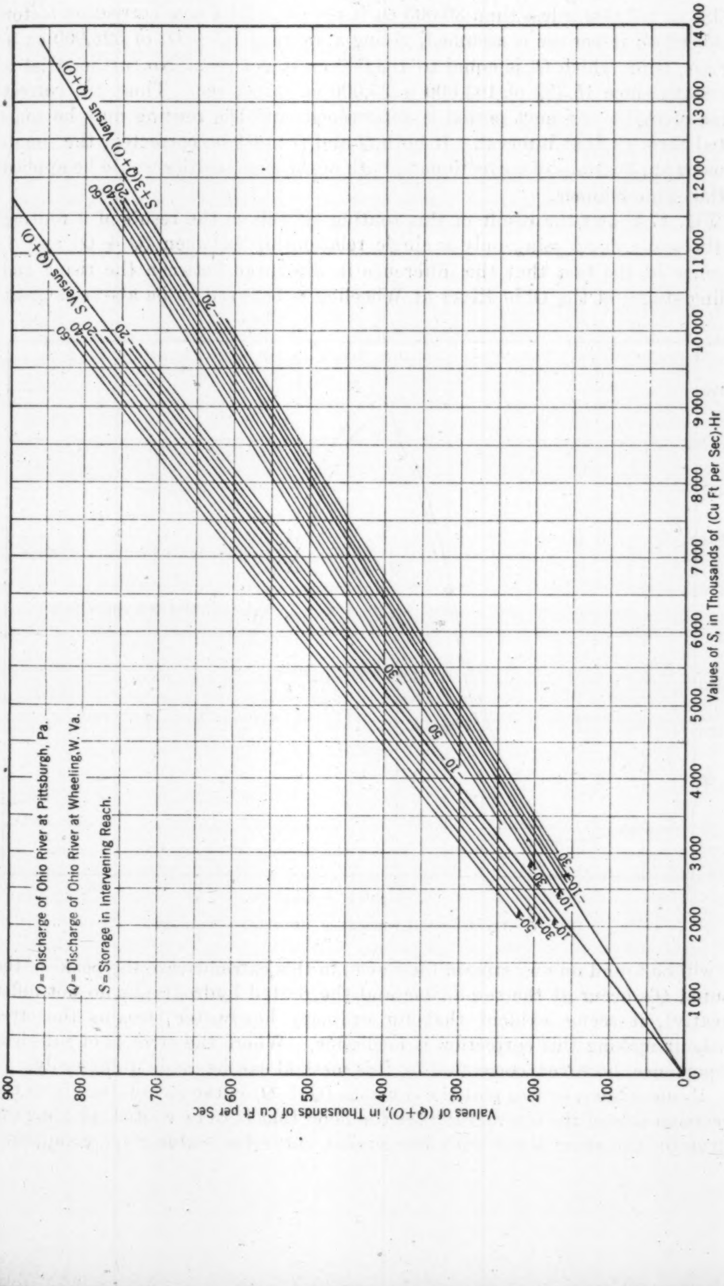

FIG. 16.—RELATION BETWEEN STORAGE AND DISCHARGE FOR STABLE RIVER CONDITIONS

per sec. Since Q is 435,000 cu ft per sec, O_1 is 167,000 cu ft per sec. However, 15.3% of 167,000 is less than 30,000 cu ft per sec, and a new correction factor of 25,000 cu ft per sec is assumed, giving a value of $(Q + O)$ of 598,000 cu ft per sec, from which O_1 is equal to 163,000 cu ft per sec. No further trial is necessary since 15.3% of 163,000 is 25,000 cu ft per sec. Thus, the correct value of O_0 for the next period is determined, and the routing may be computed through that interval. If both Q and O must be corrected, the simultaneous applications of corrections to both of these quantities would be applied in this same manner.

Fig. 17 shows the result of this routing as well as the result of a routing of the same flood using only a single relationship between $(Q + O)$ and S. In view of the fact that the difference in discharge between the rising and falling stages of the Ohio River at Wheeling is believed to be about as great as will be found on any stream (and even in this extreme case the peaks of the routed Q's occur at the same time and the routed hydrographs do not differ greatly), it seems evident that for ordinary headwater streams the error without making this correction is negligible. Where the error is of sufficient importance, however, correction by this method can be made quite easily.

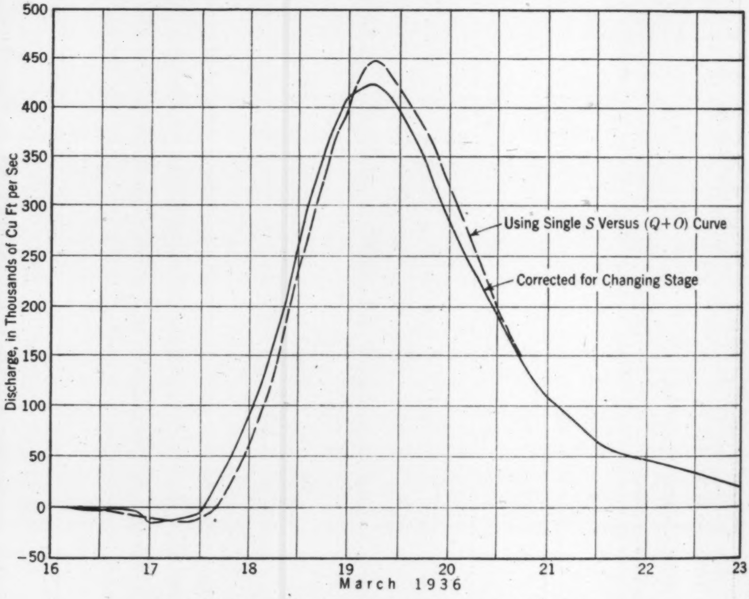

FIG. 17.—PITTSBURGH HYDROGRAPH ROUTED TO WHEELING

If one wishes, he can plot the S versus $(Q + O)$-curve as obtained from the recession side of the hydrograph for the flood that is to be routed, plotting the curve on the same sheet with the similar curve for stable river conditions.

Then after the routing has progressed until the time when the corrected values of $Q + O$ fall on this curve, it can be used for the remainder of the computations without further corrections.

In several of the discussions the question was raised as to whether or not the relationship between $(Q + O)$ and S is necessarily the same for all floods on any given basin. Some variation in this curve might be expected for floods produced by different rainfall patterns, as suggested by Messrs. Tatum and Hickman. As an illustration of the extent of this difference, four storms on the drainage area above Sewickley, Pa., were chosen for study. In these examples O is the discharge of the Ohio River at Sewickley, and Q is the sum of the discharges at Greensboro, Pa., on the Monongahela River, at Connellsville, Pa., on the Youghiogheny River, and at Parkers Landing, Pa., on the Allegheny River. Table 3 shows the discharge at each station and also that contributed by the intervening area, as well as the percentage that each is of the total Sewickley discharge. It may be observed from the table that storms of considerably different magnitude are represented and that the percentage of the total runoff contributed from each source varies over a wide range. For instance, the contribution from the intervening area ranges from 22.4% to 55.5% of the total runoff.

TABLE 3.—COMPARISON OF YIELDS FROM DIFFERENT TRIBUTARY AREAS DURING FOUR STORMS

Date	Discharge at Sewickley[a]	CONNELLSVILLE		GREENSBORO		PARKERS LANDING		INTERVENING AREA	
		Discharge[a]	%[b]	Discharge[a]	%[b]	Discharge[a]	%[b]	Discharge[a]	%[b]
March 18, 1936	21,384	2,280	10.6	4,908	22.9	2,328	10.9	11,868	55.5
October 30 1937	8,784	1,416	16.1	4,824	54.9	576	6.6	1,968	22.4
January 27, 1937	12,240	368	3.0	2,400	19.6	4,056	33.1	5,410	44.2
February 5 1939	5,856	1,008	17.2	2,712	46.2	420	7.2	1,716	29.3

[a] Discharge volumes are in 1,000 (cu ft per sec)-hr. [b] Percentage of total.

Storage-discharge curves derived from each of these storms are shown in Fig. 18. Although these curves are not identical, neither do they differ greatly. The most divergent are those for the floods of February 5, 1939, and January 27, 1937. The flood of March 18, 1936, was routed to Sewickley, using each of these two curves. The resulting routed graphs are shown in Fig. 19. It will be observed that the timing of the peak is about the same for both. The peak discharge differs by 7,000 cu ft per sec, which is about 2.3% of the total peak discharge. In this case it would seem to make little practical difference as to which of the four curves is selected for use in routing. However, even the difference between these two routed graphs does not represent an error that is inherent in the method. It represents such an error only when an S versus $(Q + O)$-curve that has been derived from the hydrograph of a flood which was produced by one particular storm pattern is used for routing a flood that resulted from a storm of a different pattern. Ordinarily, such use is unnecessary. Unless an assumed or hypothetical flood is to be routed, an S versus $(Q + O)$-curve can be derived readily and used for each different flood, and no such error will result. However, if a hypothetical flood is to be routed, its routing will depend upon the storm pattern producing it. If the pattern corresponds to any of the S versus $(Q + O)$-curves of the recorded floods of the past, then that curve can be used properly. When it is not known what storm pattern caused the hypothetical flood, the best procedure would be to route the flood by two or more of the most divergent S versus $(Q + O)$-curves obtained from past records. This procedure would show the

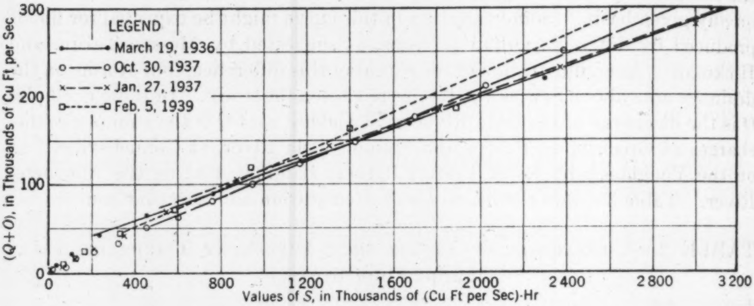

FIG. 18.—STORAGE-DISCHARGE RELATIONS DERIVED FROM FOUR FLOODS

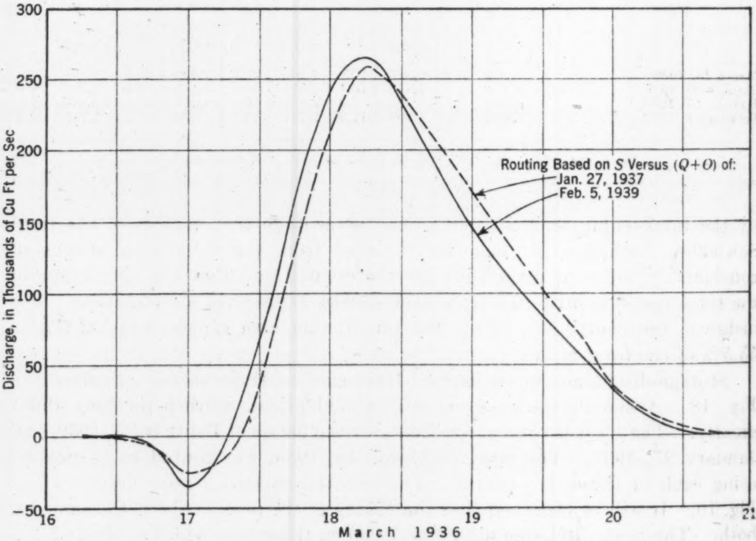

FIG. 19.—FLOOD OF MARCH, 1936, ROUTED TO DASHSHIELDS, USING S VERSUS $(Q + O)$-CURVES DERIVED FROM TWO DIFFERENT FLOODS

approximate range of results that might be expected because of different storm patterns.

The writers agree with the comment by Mr. Linsley that the check on the computed inflow, obtained by deducting the total observed upstream flow from the total observed outflow at the lower station, is only an arithmetic check. It is difficult, however, to reconcile the subsequent statement of Mr. Linsley, and also that of Messrs. Horonjeff and Crowle ("* * * the agreement of the composite of the routed hydrographs with the gaged hydrograph O at the lower end of the reach is merely a check on the arithmetical operations" and "is in no sense a check on the accuracy of the gaging at the lower station, or the correctness of the lines in Fig. 2"), with the statement of Mr. Woster that "It has been found necessary in most cases to adjust the routed hydrographs of Q and I after completion of the procedure because when they are combined they do not check, even closely, the actual hydrograph." This difference in opinion is of minor importance, however, for it involves only the question as to whether the agreement of the combined routed hydrographs with the gaged hydrograph O constitutes a bona fide check on the accuracy of the routing procedure or whether it is only a check on the arithmetic accuracy—the question of the fundamental correctness of the method is not at issue. For the sake of argument let it be granted that by the use of the two S versus $(Q + O)$-curves obtained by Messrs. Horonjeff and Crowle, and shown in Fig. 8, two different sets of routed Q-curves and I-curves will be obtained which, when combined, will coincide exactly with the measured hydrograph of O. This fact proves nothing with respect to the correctness of the method for the simple reason that the random S versus $(Q + O)$-curve does not represent the relation between S and $(Q + O)$ for the Pajaro River, whereas the other one does.

Inasmuch as the dependability of the storage equation is unquestioned, the accuracy of the Q-curve in Fig. 7 can depend only upon the following:

(*a*) The accuracy of the computations and of the discharge records at Sargent and at Chittenden;

(*b*) The correctness of the separation of the base flow from the surface runoff;

(*c*) The existence of the same relation between S and $(Q + O)$ during the rising stage as during the receding stage; and

(*d*) The use of an S versus $(Q + O)$-curve that has been derived from the flood hydrograph which is to be routed; otherwise a small and relatively unimportant error may result.

The accuracy of all methods of routing depends upon these factors. The error resulting from an incorrect separation (item (*b*)) is usually negligible and never of any great importance. This separation is necessary only for obtaining the S versus $(Q + O)$-curve. Base flow can be included in the routing operation as explained by Messrs. Horonjeff and Crowle. On streams for which the relation in item (*c*) differs excessively, the error from this source can be eliminated through the use of a loop for the expression of the relation between S and $(Q + O)$, as previously explained.

The writers are deeply indebted to Mr. Sherman for his interesting and clever suggestion for testing the validity of this method of flood routing. Mr.

Sherman's example provided an excellent check of the quantitative values of storage in the intervening reach.

Several of the observations of Mr. Brosio are decidedly at variance with the views of the writers. The significance which Mr. Brosio assigns to the quantity $\frac{S}{Q_u}$ is open to serious question. In the first place, "Q_u = uniform rate of flow, through entire reach," is a purely fictitious quantity and cannot exist in any flood-routing problem. If Mr. Brosio means to imply that, because $\frac{S}{(Q + O)}$ = a constant, this quantity "represents a constant time of travel, and, consequently, a constant mean velocity of flow irrespective of stage," it seems to the writers that this is quite a broad assumption. In this expression either Q or O can be zero without S becoming zero. If O is zero, then the expression gives the time required to provide the storage S at the average rate Q; if Q is zero, then the quantity represents the time required to deplete the storage at the average rate O; but when Q and O both have finite values, the physical significance of $\frac{S}{(Q + O)}$ is not so apparent.

It should be remembered in this connection that S, as used in the paper, represents the storage in all of the channels above Morgantown, exclusive of those above Fetterman. That this is true is apparent from the fact that it was derived by deducting from the total channel storage above Morgantown the channel storage above Fetterman. Mr. Brosio has taken the liberty of defining S as the storage in the Fetterman-to-Morgantown channel. If his definition were correct, then, of course, Mr. Brosio's conclusion that the writers had assumed that I is equal to zero would be justified.

Under the heading "II. Storage as a Function of (Inflow + Outflow)," Mr. Brosio assumes an inflow curve and then computes an outflow curve from it. He then finds certain inconsistencies in the computed outflow curve and concludes that there is something wrong with the method. The assumed inflow curve is just as glaringly inconsistent as the outflow curve. No stream ever produced such a hydrograph, but if it had it would be physically impossible for the resulting outflow hydrograph to be like the "adjusted" outflow graph shown by the short-dash line in Fig. 12. The base of the routed graph as it proceeds downstream must become broader and the crest lower. To deny this statement is to deny that velocity varies with the hydraulic radius and slope.

The statement by Mr. Hickman that "The time T should be no longer than the time of travel of the flood wave through the reach" is correct. In fact, there are reasons for believing that this time interval should be equal to the time of travel of the flood wave through the reach. However, several different routings of the same flood, in which different time intervals were used, produced nearly identical results, so it is not believed that this rule must be adhered to rigidly. Mr. Hickman suggests that

> "* * * the manner in which the flood peak moves downstream, if the intervening area were not there, is decidedly different from the manner in which the peak will move downstream under the influence of the discharge of the intervening area."

This criticism would be valid if the S versus $(Q + O)$-curve were not a straight line; but inasmuch as it is a straight line the routed flows are dependent only upon the changes in storage and not upon the actual volumes of storage existing at the different times.

Mr. Hickman further states that

> "* * * the most serious objection to the method is that it is based on the assumption that routing within a basin may depend on what has happened during one flood. Can it be said that a major storm, and the resulting flood, will proceed according to the same plan every time?"

The answer to this question is most assuredly "No!" However, the writers did not intend this paper to provide a method of determining runoff from rainfall. It is true that the hydrograph that results from any given storm depends upon the storm pattern, the condition of the ground, and a great many other factors, as Mr. Hickman states, and will therefore not proceed according to the same plan every time. It is beyond the province of flood routing, however, to start with rainfall. The basic data for this problem are flood hydrographs, either real or assumed; the determination of those hydrographs is an entirely separate and distinct problem. The problem of flood routing, as understood by the writers, is to take a flood hydrograph at an upstream station and determine when and how that hydrograph appears when it reaches a downstream station —just that and nothing more.

The most satisfactory use of the method depends upon the existence at the upper and lower stations of at least one, and preferably several, records of major floods, for it is only through records of actual performance that one is able to learn of the channel characteristics and their influence upon the flood hydrograph. The hydrographs resulting from any particular storm, and the corresponding curve of relation between S and $(Q + O)$, constitute a veritable encyclopedia of information pertaining to the characteristics of the storm pattern, drainage basin, and stream channel. To collect, in the field, all the data and to make all the measurements and computations that would be needed to derive the S versus $(Q + O)$-curve would involve a tremendous amount of work.

The actual significance of I as determined by the solution of Eq. 2 is interesting. Does this hydrograph I represent the actual rate at which overland flow from the intervening area reaches the stream channel and, if so, why is it that, when this hydrograph I is routed down to the lower station, the same hydrograph I' is obtained, regardless of whether this inflow comes from tributaries in the upper or lower reaches? The answer to this seeming inconsistency is to be found in the fact that the computed values of I represent the inflows into an imaginary reservoir located just upstream from the lower station. That this is true is indicated by the manner in which these values of I are derived. As suggested by Mr. Tatum, the hydrograph of I' could have been derived by deducting the values of Q' directly from the corresponding values of O. It may be observed that the graph I intersects I' at the crest of the latter, whereas the graph Q' reaches its peak considerably after its intersection with the graph of Q. This delayed peak in Q' is caused by the lag interval required for Q to reach the lower station, whereas there is actually no such lag in I since, from the nature of its derivation, I represents the rate of inflow in the imaginary reservoir located just above the lower station.

Several correspondents have suggested to the writers that a convincing test of the accuracy of the method could be made by routing a flood to which there was no contribution from the intervening area. Although no record could be found of a flood that exactly met that specification, the records of several floods to which the contribution from the intervening area amounted to only 15% or 20% of the total flow were found and routed. In one of these instances the total flow from the intervening area had passed the lower station before the peak occurred, and in another case very nearly all had passed ahead of the crest. In every case the routed peak occurred at the same time as the observed peak, and the graphs were nearly identical.

Perhaps others interested in this problem may have access to flood records for which there was no inflow from the intervening area. Records of floods occurring on two or more tributaries would be especially interesting and valuable, such as the North, Middle, and South rivers (tributaries to the Shenandoah River and shown in Fig. 3) with no inflow from the intervening area above Lynnwood. If one should route the flow from each of these tributaries by the use of its own S versus $(Q + O)$-curve, and then combine these routed graphs and obtain a graph that checks the recorded graph at the lower station, then surely this would constitute a bona fide check of the method. Conversely, a failure in agreement would provide similar evidence that the method is faulty, provided only (in both cases) that the discharge records are accurate.

EFFECT ON THE CHARACTERISTICS OF CENTRIFUGAL PUMPS

BY LEIGH C. FAIRBANK, JR.,[1] ESQ.

SYNOPSIS

The centrifugal pump, by merit of its principle and construction, offers one of the best means for pumping liquids containing relatively high concentrations of suspended material, as is evidenced by its wide use in dredging and mining operations and various industrial processes. However, the assumption has often been made that the total head developed by a centrifugal pump at a given discharge is independent of the concentration of foreign material carried by the liquid being pumped. Tests have proved that this assumption is erroneous, but no methods have been developed to predict this change in head. The design and choice of a pump to meet the conditions of any particular job are based upon the past performance of other pumps, operating under similar conditions, and quite frequently on the clear-water characteristics of a standard pump; this latter method, however, amounts to nothing more than a very rough estimate.

The effect of suspended material upon the head-capacity characteristics is of particular importance in the dredging field since the performance of a pipe-line dredge is dependent on the characteristics of the various units of the dredge, the prime mover, the pump, the pipe line, and the cutter head. Since the type of material handled and the head developed may vary over a wide range, it is necessary to know the effect of various materials upon the individual units if an accurate prediction or estimate of the dredge performance is to be made and the economic operating conditions are to be determined.

Past investigation of this subject is very limited, including only brief reports by the Mississippi River Commission (1)[2]; by the Japanese investigators, E. Mikumo, T. Nishihara, and M. Takahara (2); by W. B. Gregory, M. Am. Soc. C. E. (3); and by M. P. O'Brien, M. Am. Soc. C. E., and R. G. Folsom (4). These investigations established the fact that pump characteristics are different for solid-water mixtures than for water alone, but since none of these reports include a complete description of the pumps used or of the material in suspension it is impossible to make any quantitative analysis of the observed change in characteristics.

The purpose of this investigation was to obtain the characteristics of a centrifugal pump of known dimensions while pumping in suspension material of various known sizes and concentrations, and to make a quantitative analysis of the change in characteristics due to the material in suspension.

EXPERIMENTAL TESTS

The system used in conducting the experimental tests was of a recirculating type as shown in Fig. 1. The pump impeller was 12 in. in diameter, with an inlet diameter of $5\frac{1}{4}$ in. and a width of $1\frac{3}{4}$ in. The shape of the impeller vanes closely approximated the form of a logarithmic spiral of the equation

FIG. 1

$$r = e^{a\theta} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots \quad (1)$$

in which the average value of a is 0.440, r is the radius, and θ is the central angle (see Appendix I).

The suspended material used in the tests included two grades of sand and one grade of oil-well drilling mud. Specific gravity and size distribution were determined for each material in accordance with American Society for Testing Materials (A. S. T. M.) standards. Average fall velocities for the two sands were determined by weighting observed fall velocities for fractions of each sand obtained from mechanical analysis (see Table 1).

Clear-water runs were made before and after pumping each different material in suspension, for the purpose of determining the effect of wear on the pump characteristics. A complete series of runs was made at pump speeds of 1,000 and 1,200 rpm. The concentration of the suspended material was varied from 10% to 25% by net volume. Generally, the rates of discharge covered a range from 0.3 cu ft per sec to 1.0 cu ft per sec, although at the higher concentrations this lower limit could not be reached without clogging the pipe line.

TABLE 1.—RELATIVE FALL VELOCITIES

Material	Specific gravity	Median diameter, in mm	Fall velocity, in ft per sec
Monterey No. 4 sand.....	2.655	0.800	0.384
Crushed Del Monte sand..	2.630	0.034	0.0012
Mojave rotary mud.......	2.726	<0.001	....

The pump characteristics for Monterey No. 4 sand at 1,000 rpm are shown in Fig. 2, along with the clear-water characteristics for the same speed. The clear-water characteristics represent the average before and after the sand runs. These results are in keeping with the few available data on suction dredge pumps taken in the field.

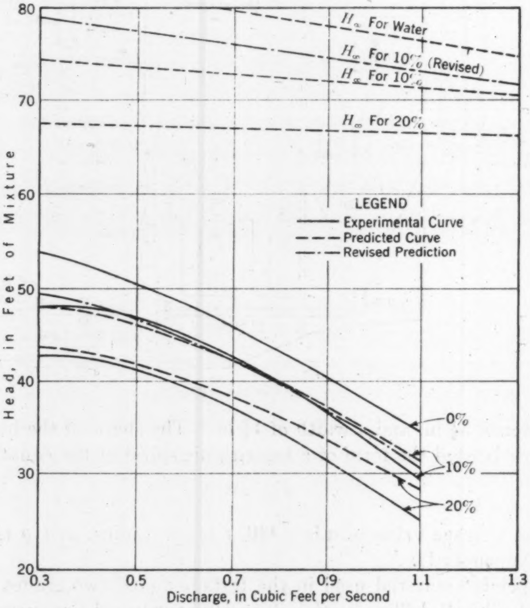

FIG. 2.—COMPARISON OF EXPERIMENTAL AND PREDICTED CHARACTERISTICS WITH MONTEREY NO. 4 SAND PUMPED AT 1,000 RPM

The head-capacity characteristics, expressed in feet of mixture, and the efficiency characteristics for the crushed Del Monte sand for all concentrations were found to coincide with the average clear-water characteristics. The ratio of power input to specific gravity of mixture also coincided with the power input characteristic for clear water. The pump characteristics for the Mojave rotary mud at 1,000 rpm are shown in Fig. 3.

The usual affinity relations for rotational speeds ($Q \propto N$, $H \propto N^2$, and $HP \propto N^3$) were applied to the solid-water characteristics at 1,000 rpm, and results compared favorably with experimental characteristics at 1,200 rpm.

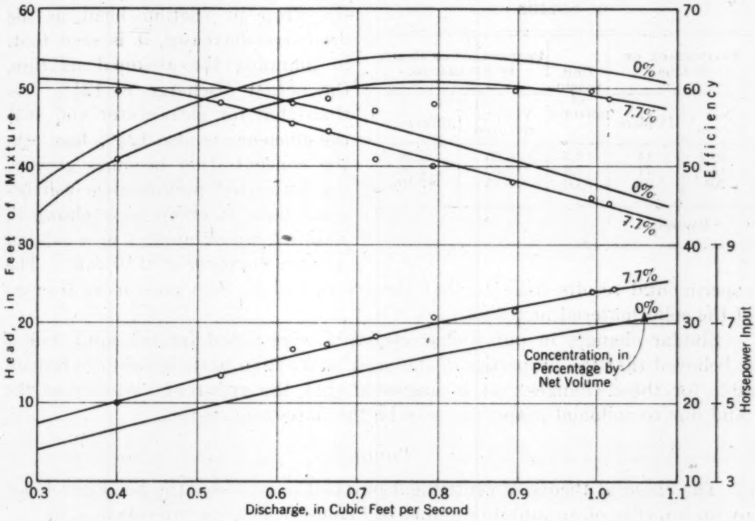

FIG. 3.—CHARACTERISTICS OF A 3-IN. DREDGE PUMP WITH MOJAVE ROTARY MUD, AT 1,000 RPM

By applying these results to a practical problem some indication is afforded as to the effect of the errors in the assumptions commonly made in the field in estimating dredge performance. If a dredge pump is assumed of the same specific speed as the pump tested herein, the characteristics of the two pumps will be proportional. Assume a dredge pump of the following description:

Description	Dimension
Dimensions of Discharge Pipe, in Ft:	
Diameter	2
Length	1,950
Discharge velocity, in ft per sec	16.3
Pump speed, in rpm	212
Impeller diameter, in ft	6.7
Static lift, in ft	30
Total head, in ft	86

The foregoing conditions correspond to the conditions of maximum efficiency, both for the test pump at 1,000 rpm and the dredge pump at 212 rpm. Assume now that the dredge is pumping a mixture consisting of 15% by net volume of

Monterey No. 4 sand. (This is equivalent to a unit weight of mixture of 77.8 lb per cu ft, the upper limit reached in dredging operations in the field.) In ordinary practice the rate of discharge and efficiency of the dredge pump would be estimated as the same as for clear water. However, referring to Fig. 2, and taking into account the drop in friction head as the discharge decreases, it is seen that, in pumping the assumed mixture, the actual discharge is 12½% less than that for clear water and that the efficiency is also 12½% less. As the concentration becomes greater, the estimated performance will become more in error, as is shown in Table 2, which applies to a sand of median diameter of 0.80 mm. The experimental results indicate that the errors will become greater as the size of the solid material increases.

TABLE 2.—ESTIMATED PERFORMANCE WITH VARYING PERCENTAGES OF SOLIDS

Percentage of Solids		Unit weight of mixture	Percentage of Error in Estimated:	
Net volume	In place		Yardage removed	Efficiency
10	14	72.5	6.25	9.38
15	21	77.8	12.50	12.50
20[a]	28	83.0	18.75	17.19

[a] Excessive.

Similar changes in pump characteristics were noted for the mud, but it is believed that the properties of the mud, other than particle size, are responsible for these changes. It is suggested that the apparent viscosity of the mud due to colloidal properties may be the important factor.

THEORY

The classical theory of centrifugal pumps (5) expresses the head developed by an impeller of an infinite number of blades, neglecting pre-rotation, as

$$H_\infty = \frac{U_2 v_{u2}}{g} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (2)$$

in which H_∞ is the head, in feet of fluid, U_2 is peripheral velocity of impeller, and v_{u2} is the tangential component of the absolute velocity at exit from the impeller. Eq. 2 gives the head in feet of fluid being pumped. To derive an expression for the actual head developed by a pump, it is necessary to include certain losses occurring both within the impeller and within the pump casing. Experiments indicate, however, that these losses are similar for both sand-water mixtures and clear water.

Referring to Eq. 2, it is seen that under conditions of constant speed the only manner in which the head developed could become less is that in which the value of v_{u2} also decreases. Since experiments indicate that for a sand-water mixture the head developed is less than that for water alone, at the same discharge, then the loss must be due to a decrease in the value of v_{u2} for the solid-water mixture, or, in other words, the solid particle must leave the impeller with a greater relative velocity than the water particles. This is shown graphically in Fig. 4.

From the geometry of the velocity diagrams at the exit from the impeller, in which $V_{f(2)}$ is the radial component of relative velocity with respect to the impeller blade at the exit, and β is the blade angle:

$$v_{u2} = U_2 - V_{f(2)} \cot \beta \qquad (3)$$

Assume an impeller of an infinite number of blades and add to the assumptions made in the classical theory the assumption that the solid particles also travel a relative path that follows the contour of the vanes. Then an expression

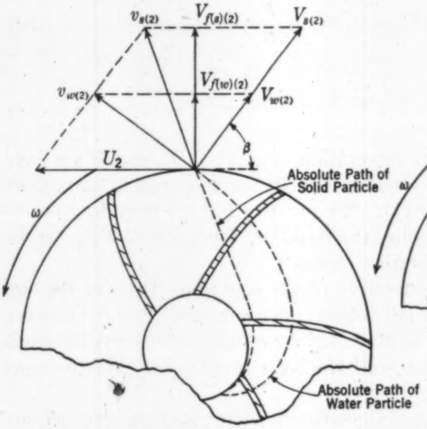

FIG. 4.—VELOCITY DIAGRAMS OF SOLID AND WATER PARTICLES AT EXIT FROM IMPELLER

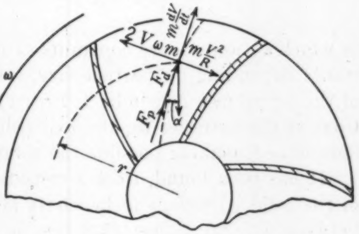

FIG. 5.—DIAGRAM OF FORCES ACTING ON SOLID PARTICLES PASSING THROUGH IMPELLER

can be obtained for the head developed by the impeller by adding the expressions for power imparted to the water and to the solid particles (which are determined from the time rate of change of moment of momentum), equating this sum to the expression for total power (which equals the product of the discharge per unit time, the unit weight of the mixture, and the head developed in feet of mixture), and then solving for the value of this head. Performing the foregoing operations, the expression for the theoretical head is obtained, expressed in feet of mixture,

$$H_\infty = \frac{S_s\, p_s\, U_2\, (U_2 - V_{f(s)(2)} \cot \beta) + (1 - p_s)\, U_2\, (U_2 - V_{f(w)(2)} \cot \beta)}{g\, S_a} \qquad (4)$$

In Eq. 4, subscript s refers to solid particles, w to water particles, 2 to the exit from the impeller, a to the average of solid-water mixture, S is specific gravity, and p is concentration of solids in percentage by volume.

The solution of Eq. 4 requires the value of $V_{f(w)(2)}$, which can be determined by the continuity relationship on the basis that the impeller is completely filled with water, and the value of $V_{f(s)(2)}$, which is not so readily determined.

Referring to Fig. 5, which shows the forces acting on a solid particle in a fluid at any position within the impeller, it is seen that there are six forces acting. If the forces acting tangent to the impeller vane are equated:

$$m \frac{dV_s}{dt} = m\, \omega^2\, r \cos \alpha - F_d - F_p \qquad (5)$$

in which m is the mass of a solid particle and ω is the angular velocity of the impeller. By assuming that F_d is a viscous force, that F_p is the force due to the pressure gradient in the fluid surrounding the particle, and that the impeller vane approximates a logarithmic spiral, and by taking an average value of V_w as it appears in the expressions for F_d and F_p, it is possible to obtain the following equations describing the motion of the solid particle:

$$r = C_1 e^{Xt} + C_2 e^{Yt} - \frac{F}{B} \qquad (6a)$$

and

$$V_s = \frac{\sqrt{1 + a^2}}{a} (C_1 X e^{Xt} + C_2 Y e^{Yt}) \qquad (6b)$$

in which C_1 and C_2 are constants of integration, and X, Y, F, and B are constants depending on particle size, settling velocity, and operating conditions of the pump (see Appendix I, Eqs. 11). By substituting the boundary conditions at the entrance to, and exit from, the impeller, the value of $V_{s(2)}$ can be determined, making possible the solution of Eq. 4.

It has been found, from a consideration of the equations, that, as the size of the solid particle, and hence its fall velocity, become smaller, the difference between V_s and V_w becomes less, so that, for very small solid particles (such as crushed Del Monte sand) in suspension, the head developed will be the same as for water alone.

The predictions of the operating characteristics while pumping a suspension may be obtained by expressing the difference between H_∞ as computed by Eq. 4 and H_∞ for clear water as a percentage loss, and applying this loss to the actual clear-water characteristics of the pump.

A comparison between predicted and test characteristics for Monterey No. 4 sand at 1,000 rpm is given in Fig. 6. For the rating point of the pump the predicted characteristic is correct for a concentration of 10% by net volume and is within 5% of the test value for a concentration of 20%. This same agreement was found to hold true at 1,200 rpm. A sample computation for this prediction is given in Appendix I.

The errors introduced through the assumptions made in this discussion are well appreciated. For the most part they are the same as those made in the classical theory, which are well known to be in error and for which it is possible to make corrections. Probably the least valid of the assumptions, at least when the suspended material has a high settling velocity, is that as to the nature of the resistance force between the solid and water particles. It is a well-known fact that Stokes' law is valid only in the range of Reynolds' number less than 0.50, and, since this value is probably greatly exceeded in most cases, it would be more nearly correct to use Rittenger's or Allen's law (6). However, the application of such a law involves the solution of a complicated differential equation. For the pump and suspended material used in the experimental tests, values of H_∞ were computed by a trial-and-error method, using Rittenger's law. These values were about 7% higher than those determined by the less accurate solution. However, if the difference between H_∞ for water and H_∞ for the suspension, computed by trial and error, is applied directly as a loss to the actual clear-water characteristics, the predicted characteristics for the suspension agree within 4% with the experimental characteristics. This agreement is shown in Fig. 6. In view of the increased difficulty and expenditure of time in making the trial-and-error solution, the method first described is the more practical, especially since both methods are subject to several approximations.

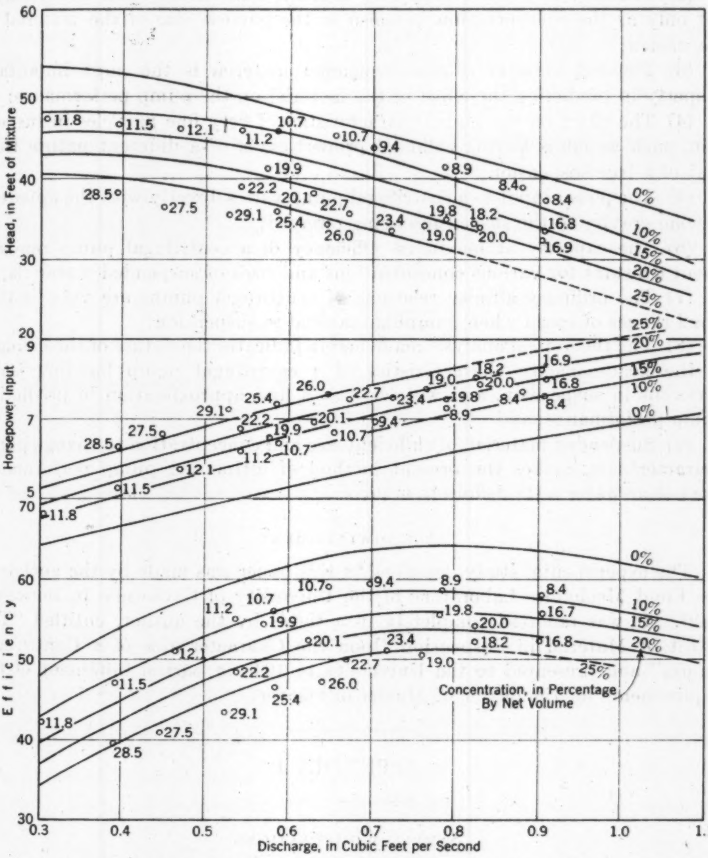

FIG. 6.—CHARACTERISTICS OF A 3-IN. DREDGE PUMP WITH MONTEREY NO. 4 SAND, AT 1,000 RPM

CONCLUSIONS

The following conclusions are based on the observations made in this investigation:

(1) At a given capacity the head developed, in feet of mixture, by a centrifugal pump handling material in suspension, is less than that developed for water alone;

(2) The drop in the head-capacity characteristics at constant speed varies not only as the concentration but also as the particle size of the material in suspension;

(3) The fall velocity of the suspended material is the most important property in predicting the effect of the material on the pump performance;

(4) The effect on the pump characteristics of very fine particles in suspension, such as muds having colloidal properties, is of a different nature than that of a true suspension;

(5) The power input to a centrifugal pump varies directly with the apparent specific gravity of the suspension being pumped;

(6) The capacity at maximum efficiency of a centrifugal pump remains about constant for various concentrations and sizes of suspended materials;

(7) The ordinary affinity relations of centrifugal pumps are valid within small ranges of speed when pumping material in suspension;

(8) The theoretical analysis made herein indicates the nature of the changes in the head-capacity characteristics of a centrifugal pump handling solid materials in suspension, and will serve as a first approximation in predicting pump performance; and

(9) Suspended material, of sufficient size and concentration to change pump characteristics, makes the present method of estimating pump performance from clear-water tests definitely in error.

ACKNOWLEDGMENT

The experimental study described in this paper was made by the author in the Fluid Mechanics Laboratory of the University of California, in Berkeley, Calif. It was reported completely in a thesis by the author, entitled "The Effect of Material in Suspension Upon the Characteristics of a Centrifugal Pump," and presented to the University in 1940 in partial fulfilment of the requirements for the degree of Master of Science.

APPENDIX I

SAMPLE COMPUTATIONS

In order to make a sample computation it will be necessary to review briefly the steps in deriving Eq. 5 so as to determine the constants X, Y, F, and B. The term F_p which appears in Eq. 5 will be neglected since, for the particular material in suspension, this term affected the solution of that formula only 0.5%. From the assumption that F_d is a viscous force, Stokes' law states

$$F_d = K\,(V_s - V_w) \qquad (7)$$

From the assumption that the impeller vane is a logarithmic spiral: $r = e^{a\theta}$

(Eq. 1); cos α = a constant; and

$$V_s = \frac{dr}{dt}\frac{\sqrt{1 + a^2}}{a} \qquad (8)$$

By taking an average value of V_w as it appears in Stokes' law, Eq. 5 may be written:

$$\frac{d^2r}{dt^2} = \frac{a\,\omega^2\,r \cos\alpha}{\sqrt{1 + a^2}} - \frac{K}{m}\frac{dr}{dt} + \frac{a\,K\,V_{(w)\,\text{average}}}{m\,\sqrt{1 + a^2}} \qquad (9)$$

Let:

$$A = \frac{K}{m} \qquad (10a)$$

$$B = -\frac{\omega^2\,a \cos\alpha}{\sqrt{1 + a^2}} \qquad (10b)$$

and

$$F = -\frac{a\,K\,V_{(w)\,\text{average}}}{m\,\sqrt{1 + a^2}} \qquad (10c)$$

Substituting Eqs. 10 in Eq. 9:

$$r = C_1\,e^{Xt} + C_2\,e^{Yt} - \frac{F}{B} \qquad (6a)$$

and

$$V_s = \frac{\sqrt{1 + a^2}}{a}\,(C_1\,X\,e^{Xt} + C_2\,Y\,e^{Yt}) \qquad (6b)$$

in which (to simplify typography):

$$X = \tfrac{1}{2}\,(-A + \sqrt{A^2 - 4B}) \qquad (11a)$$

and

$$Y = \tfrac{1}{2}\,(-A - \sqrt{A^2 - 4B}) \qquad (11b)$$

The physical properties of the pump are:

a = 0.44 (the constant in equation of a logarithmic spiral);
r_1 = 0.167 ft (inlet radius of impeller);
r_2 = 0.500 ft (exit radius of impeller);
b_1 = 0.183 ft (width of impeller passage at inlet);
b_2 = 0.146 ft (width of impeller passage at exit);
A_1 = 0.192 sq ft (area of impeller passage at inlet);
A_2 = 0.459 sq ft (area of impeller passage at exit);
α = 66° 16′ (from the equation of the blade; the acute angle between the tangent to the blade and the radius of the impeller);
β = 23° 44′ (from the equation of the blade; blade angle at 1,000 rpm);
ω = 104.72 radians per sec (angular velocity of impeller); and
U_2 = 52.36 ft per sec (peripheral velocity of impeller).

The physical properties of Monterey No. 4 sand are: Median diameter, D = 0.800 mm; fall velocity, v = 0.384 ft per sec; and specific gravity, S_s

= 2.655. From Stokes' law—

$$K\,v = \frac{\pi\,D^3}{6}\,(S_s - 1)\,w \qquad (12)$$

Also, the mass of a solid particle is

$$m = \frac{\pi\,D^3\,S_s\,w}{6\,g} \qquad (13)$$

and $\frac{K}{m} = 52.271$.

Assume a pump speed of 1,000 rpm, a discharge of 1 cu ft per sec, and a concentration of sand of 10% by net volume. Substituting in Eqs. 10 and 11: $A = \frac{K}{m} = 52.271$; $B = -1{,}776.603$; $F = -174.188$; $\frac{F}{B} = 0.098$; $X = 23.460$; and $Y = -75.731$.

When $r = r_1 = 0.167$ ft, $t = 0$ and $V_{s(1)} = \frac{Q}{A_1}\sin\beta = 12.956$ ft per sec. Substituting in Eq. 6*a*:

$$0.167 = C_1 + C_2 - 0.098 \qquad (14a)$$

Substituting in Eq. 6*b*:

$$5.221 = 23.460\,C_1 - 75.731\,C_2 \qquad (14b)$$

Solving for C_1 and C_2: $C_1 = 0.255$ and $C_2 = 0.010$.

When $r = r_2 = 0.500$ ft, substitute in Eq. 6*a*: $0.500 = 0.255\,e^{23.460t} + 0.010\,e^{-75.731t} - 0.098$; and $t_2 = 0.0362$ sec. Substituting in Eq. 6*b*: $V_{s(2)} = 34.536$ ft per sec. Furthermore, $V_{f(s)(2)} = V_{s(2)}\sin\beta = 13.928$ ft per sec; and $V_{f(w)(2)} = \frac{Q_w}{A_2} = 1.961$ ft per sec. Substituting in Eq. 4: $H_\infty = 67.809$ ft, for Monterey No. 4 sand, at 1,000 rpm, 1 cu ft per sec, and 10% concentration. Repeating the foregoing steps for the same conditions but for a discharge of 0.3 cu ft per sec, $H_\infty = 73.195$ ft.

It is to be noted that the foregoing results vary with those shown in Fig. 6 but give a much better agreement between the predicted and actual characteristics.

MECHANICS OF FLOW, WITH NONCOLLOIDAL, INERT SOLIDS

By Warren E. Wilson,[3] Assoc. M. Am. Soc. C. E.

Synopsis

The investigation of the laws governing the pipe-line flow of liquids containing solids in suspension has received the attention of a number of investigators in several fields. The presentation and analysis of the data in most cases have been of such a nature as to provide essentially an immediate answer to questions concerning the efficiency of the pumping process. Little progress has been made toward the unification of the data by means of a comprehensive theoretical background.

In the field of the transportation of solids by streams in open channels notable work has been done by a number of men, prominent among whom are Morrough P. O'Brien and E. W. Lane, Members, Am. Soc. C. E., and J. E. Christiansen, A. A. Kalinske, and Hunter Rouse, Assoc. Members, Am. Soc. C. E., to provide a clearer understanding of the mechanics of the turbulence process in maintaining material in suspension. However, a direct application of their approach to the problem of the transportation of solids in pipes does not seem feasible at the present time.

The purpose of this study is to provide an elementary theory on the basis of which certain features of the available experimental data on the transportation of solids in pipes may be interpreted. The theory is neither complete nor directly concerned with the details of the mechanics of the turbulence process in maintaining solids in suspension, but rather represents an analysis of the mechanics of the flow on the basis of energy relationships; and it results in an explanation of several important and previously noted but unsatisfactorily explained features of the flow.

Experimental data from several sources are presented and analyzed on the basis of the background provided by the theory. Due to lack of complete data in many old studies of flow of the type under consideration it is impossible to make use of the results of much of the experimental work.

Theory

The analysis will be limited to the consideration of the transportation of noncolloidal, inert solids for which the average velocity of settling relative to the transporting liquid is known. Complicating factors such as chemical reaction between solids and liquid and the formation of semi-solid plugs, as noted by some observers, will be assumed negligible or nonexistent.

---

[3] Prof. and Head, Dept. of Mechanics, Colorado School of Mines, Golden, Colo.

Consider a liquid flowing in a horizontal pipe, as illustrated in Fig. 7, toward the right at the constant average velocity V. Particles such as P are in suspension. If there were no turbulence the particle P would settle at the velocity V_s and in the period of time T would move downstream the distance $L = V\,T$ and vertically downward the distance $V_s\,T$. The flow being steady the particles will maintain their average positions in the vertical relative to the pipe wall. Now, since the particles individually do settle and are raised up to new positions by the turbulence of the liquid, maintaining the same average position, it is clear that the liquid must do work on the particles definitely related to the decrease in potential energy due to settling. It is not to be expected that the work done is exactly equal to this change in potential energy since the motion of the particles in settling relative to the liquid is accompanied by a loss in mechanical energy of the particles due to the viscosity of the liquid. Similarly additional energy will be required in raising the particles due to the viscous resistance requiring that more work be done than is necessary to raise the particles vertically a given distance.

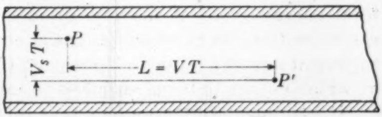

FIG. 7

In order to express this relationship between work done by the liquid on the particles in maintaining the suspension, and the decrease in potential energy during settling, one may write:[3a]

$$K_p\,A\,L\,V_s\,T\,w_e = w\,h_1\,A\,L \qquad (15)$$

in which: A is the cross sectional area of the flow section; p is the weight of solids per unit weight of solid-liquid mixture; w is the unit weight of the mixture; w_e is the effective weight of the particles suspended in the liquid; K_p is a coefficient associated with the efficiency of the process; and h_1 is the decrease in the elevation of the energy grade line in the length L due to the maintenance of the solids in suspension. Now recalling that

$$L = V\,T \qquad (16)$$

Eq. 15 may be simplified into the form,

$$\frac{h_1}{L} = \frac{K\,p\,V_s}{V} \qquad (17)$$

which is a very simple expression for the slope of the energy gradient due to the maintenance of the solids in suspension.

The Weisbach-Darcy equation may be used to determine the slope of the energy gradient due to the resistance of a homogeneous liquid flowing in a given pipe, and it will be assumed that this equation will apply equally well to a non-homogeneous liquid-solid mixture. Therefore,

$$\frac{h_2}{L} = \frac{f\,V^2}{2\,g\,D} \qquad (18)$$

[3a] Note corrections to Eq. 15 given in the closing discussion on page 1593.

in which: f is the friction factor; D is the pipe diameter; $\frac{h_2}{L}$ is the slope of the energy gradient due to the flow of the liquid mixture expressed in feet of mixture per foot of pipe; and g is the acceleration due to gravity.

An expression for total energy gradient follows immediately from the addition of Eqs. 17 and 18—

$$\frac{H}{L} = \frac{f\,V^2}{2\,g\,D} + \frac{K\,p\,V_s}{V} \qquad (19)$$

Eq. 19 expresses the fundamental principle of this study, the concept that the total energy gradient may be divided into two parts—the first, that which expresses the rate at which potential energy is being dissipated to maintain the turbulent flow of a liquid in a pipe, and the second, that which expresses the rate at which energy is being supplied to maintain the solids in suspension.

It is immediately apparent that for a given pipe, percentage of solids, and particle size and shape which are characterized by V_s, the total energy gradient approaches that for a clear liquid as V increases, since the second term of Eq. 19 decreases as V increases and the first term is the energy gradient for a clear liquid expressed in terms of head of the mixture per unit length of pipe. This phenomenon has been repeatedly observed by investigators in this field.

It is evident also that for a given solid-liquid mixture and size of pipe there will be a velocity that gives a lesser energy gradient than any other velocity. The approximate magnitude of this velocity may be determined by assuming p, V_s, f, K, and D constant, then differentiating the expression for $\frac{H}{L}$ with respect to V and setting the first derivative equal to zero. The resulting criterion for the critical value of the velocity is,

$$V^3_c = \frac{K\,p\,V_s\,g\,D}{f} \qquad (20)$$

in which V_c is the critical velocity, giving minimum energy gradient for the given combination of pipe and mixture.

Thus far it has been assumed that all the solids remain in suspension. However, it is apparent and a matter of common observation that under certain circumstances the solids will settle out, and eventually clog the pipe. The criterion for settling out of the particles or the picking-up of particles from the bed has been discussed by Messrs. Lane and Kalinske.[4] These writers demonstrate that, if the quantity $\frac{V'_s}{\sqrt{\frac{\tau_0}{\rho}}}$ (in which V'_s is the settling velocity of the solids, τ_0 is the bottom shearing stress per unit area, and ρ is the unit density of the liquid) is equal to or greater than unity little or none of the material with settling velocity V'_s will be placed in suspension.

---

[4] "Relation of Suspended to Bed Material in Rivers," by E. W. Lane and A. A. Kalinske, *Transactions*, Am. Geophysical Union, 1939, p. 637.

Assuming that the shearing stress τ_0 is equal for all parts of the wetted perimeter it follows that, for an element of the liquid, of length L and diameter D_l, the equation of equilibrium in the direction of flow is:

$$(p_1 - p_2)\frac{\pi D^2_l}{4} - \tau_0 \pi D_l L = 0 \ldots\ldots\ldots\ldots\ldots \tag{21}$$

in which p_1 and p_2 are the unit pressures at the upstream and downstream ends of the element, respectively. If H is the decrease in pressure head in the length L, it follows that

$$\frac{\tau_0}{\rho} = \frac{H g D_l}{4 L} \ldots\ldots\ldots\ldots\ldots\ldots \tag{22a}$$

or upon substitution of the hydraulic radius for 0.25 D_l:

$$\frac{\tau_0}{\rho} = \frac{H g R}{L} \ldots\ldots\ldots\ldots\ldots\ldots \tag{22b}$$

which will give for the quantity $\sqrt{\frac{\tau_0}{\rho}}$ the expression,

$$\sqrt{\frac{\tau_0}{\rho}} = \sqrt{\frac{H g R}{L}} \ldots\ldots\ldots\ldots\ldots\ldots \tag{23}$$

Thus, the condition for the settlement of solids becomes,

$$\frac{V'_s}{\sqrt{\frac{H g R}{L}}} = 1 \ldots\ldots\ldots\ldots\ldots\ldots \tag{24}$$

The assumption of uniform shear stress around the wetted perimeter is not likely to be fulfilled and there will be settling out of solids at values of the ratio of Eq. 24 corresponding to velocities somewhat different from those indicated by a value of unity of the ratio.

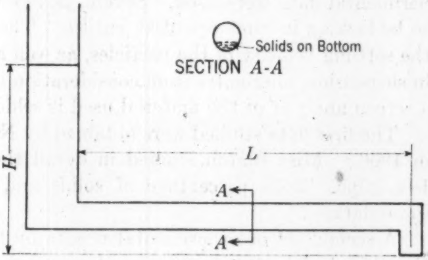

FIG. 8

Although some data are available concerning the minimum velocities necessary to prevent clogging the auxiliary data are incomplete and afford no basis for checking the validity of Eq. 24.

A means of determining the suitability of Eq. 24 as a criterion for deposition of solids was made possible by the observations on the flow in the tailings disposal line of the Climax Molybdenum plant at Climax, Colo. The important characteristics of the situation that exists in this pipe line are depicted in Fig. 8. Since the flow in this line represents a type entirely different from that in pipe which is commonly supplied by a pump, it merits consideration under this section, setting forth the elements of the mechanics of the flow of solids suspended in liquids in pipe lines.

Fig. 8 illustrates a horizontal pipe fed from a vertical stand-pipe open to the atmosphere, and discharging from a right-angled bend, vertically downward. The elevation of the free surface in the stand-pipe is determined by the loss of head in the pipe line. This loss, in turn, is dependent upon all the factors indicated by Eq. 19. It is apparent that if the discharge, percentage of solids, or type or size of particles changes the head loss will change. An automatic adjustment of the head takes place in the case of any of these changes and the flow eventually becomes steady. It is apparent that if, with a given discharge, the velocity is so low that solid particles are deposited on the bottom, this deposition will continue until the cross section has become obstructed to such an extent that the velocity is high enough to maintain the suspension, and the pipe will not clog since the head will automatically adjust itself to the new steady state. Such is found to be the mode of operation of this pipe line. Obviously a pipe supplied from a pump that maintains a constant head could not operate in this manner since the automatic head adjustment would not be possible.

Thus far, a horizontal pipe has been assumed. If the slope of the pipe is very large the component of the settling velocity perpendicular to the pipe wall must be considered as the quantity V_s rather than the full vertical velocity with which the solids settle relative to the liquid. In the case of small slopes this factor will be of minor importance but will doubtless be a factor of considerable importance if the slope is very large. If the pipe is vertical, obviously there is no component of the settling velocity perpendicular to the pipe wall; hence, in this case, one would expect no increase in the energy gradient due to the maintenance of the suspension.

DESCRIPTION OF EXPERIMENTAL DATA

To investigate the applicability of the foregoing theory, three sets of experimental data were used. Several others were investigated but were found to be lacking in some essential feature. The fact that it is necessary to know the settling velocity of the particles, as well as the percentage of solid material in suspension, eliminates from consideration much data that are available since a screen analysis of the material used is seldom available.

The first data studied were obtained by Nora Stanton Blatch and published in 1906.[5] Miss Blatch studied in detail the flow of sand-water mixtures in 1-in. pipe. Both percentage of solids and screen analysis are available in these data.

A second set of experimental results by G. W. Howard, Jun. Am. Soc. C. E., published in 1939,[6] contains data on the flow of sand-water and gravel-water mixtures in 4-in. pipe. These data are complete with screen analyses.

A third set of data (see Table 3) was supplied by the Climax (Colo.) Molybdenum Company and is complete in practically every detail. This material describes the flow of tailings in an 18-in. wood-stave pipe line so constructed and connected as to give a unique flow of the mixture differing in several important respects from the flow in the conventional pipe line setup.

---

[5] *Transactions*, Am. Soc. C. E., Vol. LVII, December, 1906, pp. 400–408.

[6] *Loc. cit.*, Vol. 104 (1939), pp. 1334–1348; also, *loc. cit.*, Vol. 106 (1941), pp. 135–157.

The essential data are introduced in the following sections when necessary for the discussion. The settling velocity (Table 3) in all cases was estimated on the basis of the grain size only and no allowance was made for shape of particles; hence, the data may well be in error to some extent. However, this fact will not materially detract from the value of the conclusions drawn.

Analysis of Data

Fig. 9 is a plot of the experimental data assembled by Miss Blatch. The head loss in a 1-in. pipe per unit length, expressed in terms of the head of the mixture, is plotted as the ordinate and the average velocity of the mixture in the pipe is plotted as the abscissa. Each curve represents the data for the flow with a given average settling velocity of particles in the mixture and a given percentage of solids.

Sands designated as Nos. 1 and 2, respectively, were used in the work done by Miss Blatch. All of sand No. 1 passed the 20-mesh and was retained on the 40-mesh sieve. It is estimated that the average settling velocity of this material in water was 0.213 ft per sec. Sand No. 2 all passed the 60-mesh and was retained on the 100-mesh

[a] Velocity determined by adding salt to the intake of the penstock, analyzing the pipe discharge for chlorine and noting the time for salt to appear at the discharge end.

[b] The tailing on this grind and density surged in the penstock; evidence of a tendency to become choked.

[c] Average free area; the part of the pipe area required to carry the given volume at a determined velocity.

sieve. It is estimated that the average settling velocity of this material in water was 0.0655 ft per sec.

In Fig. 9 it is easily seen that the important characteristics of the flow of the sand-water mixtures are in essential agreement with the predictions of the foregoing theory. Each curve, representing individually a given mixture, shows the characteristic minimum energy gradient at a certain velocity, with the exception of the curve for $V_s = 0.21$ ft per sec and $p = 0.12$ which does not clearly show such a minimum. Although the curves do not all become asymptotic to the curve for clear water, and in some cases drop below the clear-water curve, the general tendency is as predicted and the explanation for the dropping below the clear-water curve is doubtless that the presence of the solids modifies the characteristics of the flow to such an extent that the energy gradient for the mixture is no longer comparable to that for clear water. The presence of the solids has been thought to act as a damping influence on the turbulent fluctuations of the velocity thus decreasing the energy gradient.

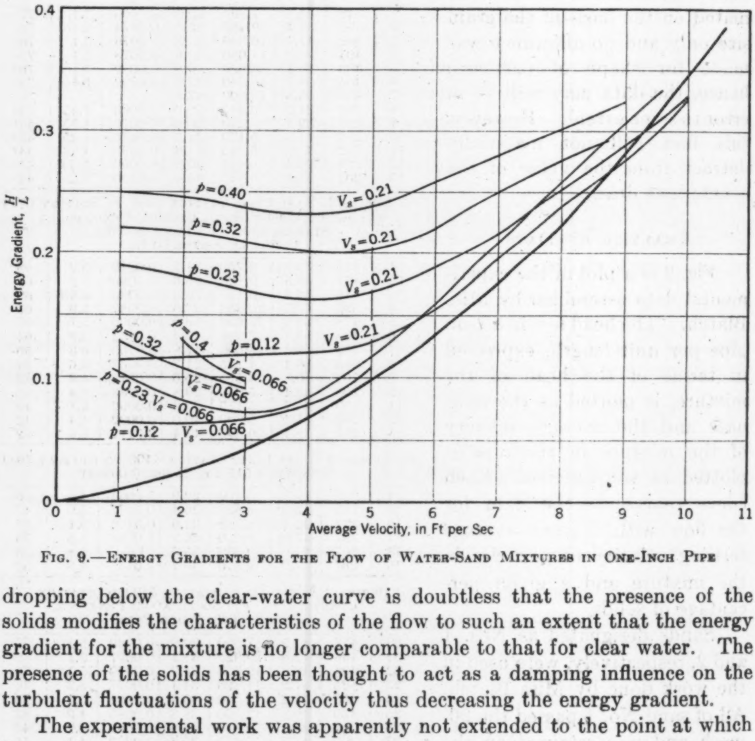

FIG. 9.—ENERGY GRADIENTS FOR THE FLOW OF WATER-SAND MIXTURES IN ONE-INCH PIPE

The experimental work was apparently not extended to the point at which it would be possible to determine the clogging velocities for the various mixtures. Therefore, it is impossible to learn anything concerning the applicability of the criterion for settling of the solids.

It is important to note that, in general, the head loss is a function of velocity at low velocities, and as had been observed in some experimental work independent of velocity over only small ranges of velocity. The variation of the head loss with velocity in the low velocity range is small in some cases.

Fig. 10 is similar to that of Fig. 9 and depicts the data obtained by Mr. Howard, who used a 4-in. pipe and a sand for which he presented a screen analysis. On the basis of the screen analysis it is estimated that the average settling velocity of the sand in water is 0.16 ft per sec.

The same general characteristics which were indicated by Miss Blatch's data are discernible in Mr. Howard's work, but the fact that the data cover a relatively narrow velocity range precludes the exact determination of the velocity for minimum head loss. The clogging velocities, experimentally determined by Mr. Howard, are indicated on the diagram by the short vertical lines so marked.

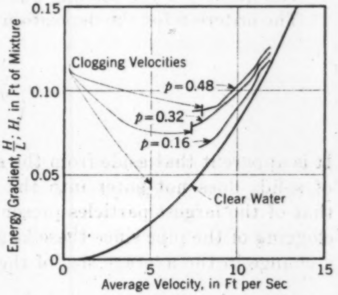

FIG. 10.—ENERGY GRADIENTS FOR THE FLOW OF WATER-SAND MIXTURES IN FOUR-INCH PIPE (AVERAGE SETTLING VELOCITY, V_s = 0.16 FT PER SEC)

Fig. 11 shows a graphical representation of the data observed at Climax. The slope of the energy gradient is plotted as the ordinate and the quantity $\frac{p\,V_s}{V}$ as abscissa. The points are grouped according to approximately equal rates of discharge since the data were gathered by maintaining nearly constant rates of discharge with varying solids content in each series of runs. The data cover so narrow a range of velocities that a plotting of the type shown in Figs. 9 and 10 is not possible.

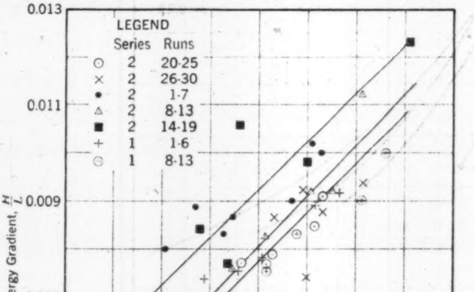

FIG. 11.—ENERGY GRADIENTS FOR THE FLOW OF TAILINGS IN 18-IN. WOOD-STAVE PIPE (f COMPUTED FOR A GIVEN DISCHARGE AND APPARENT $\frac{H}{L}$ FOR ZERO SOLIDS CONTENT)

In each series of runs both the percentage and size of solids were varied. Corresponding changes in the slope of the energy grade line took place. These data are summarized in Table 3. It is interesting to note that for a given discharge and with varying percentages and sizes of solids, the average velocity in the cross section remains nearly constant. In other words, the variation in the quantity and average size of the solids had a minor effect upon the amount of deposition of material. This is in accordance with the conditions for the settling out of the solids.

The criterion for the deposition of solids from the suspension is expressed as

$$\frac{V_s}{\left(\frac{g\,r\,H}{L}\right)^{0.5}} = 1 \qquad (25)$$

It is apparent that aside from the effect on the energy gradient, the percentage of solids does not enter into the consideration. The settling velocity V_s is that of the largest particles present in sufficient quantity to be a factor in the clogging of the pipe since these large solids would settle first. Evidently, then, a change in the average size of the particles need not greatly affect this maximum settling velocity. The fact was observed that the open area of the cross section and average velocity changed little for a given discharge when the solids content was varied over a wide range. This phenomenon is explained satisfactorily on the basis of a slight change in the maximum settling velocity and an increase in the energy gradient sufficient in amount to compensate for the increase that did take place. The increase in the energy gradient is due to the increase in the value of the quantity $\frac{p\,V_s}{V}$ upon which, as may be seen in Eq. 19, the energy gradient is directly dependent.

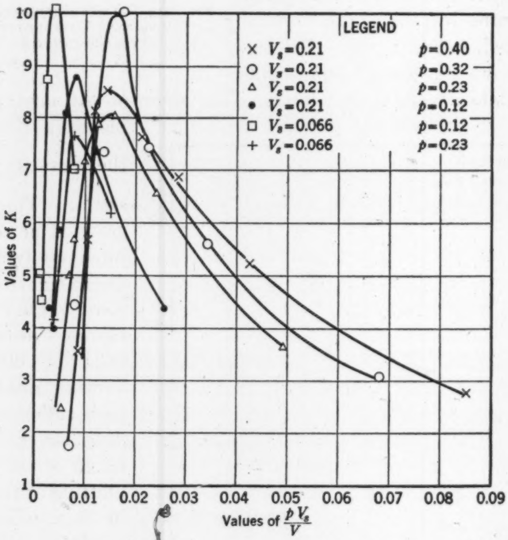

FIG. 12.—COEFFICIENT K AS A FUNCTION OF THE QUANTITY $\frac{p\,V_s}{V}$

The plotting of Fig. 11 indicates a value of the coefficient K of very nearly unity in most cases. The solid lines drawn through the groups of points have slopes which, in most cases, are approximately equal to 1. A slope of $S = 1$ corresponds to $K = 1$. The indicated values of f, the coefficient of Darcy's equation for pipe flow, were computed on the basis of the energy gradient for zero solids content as determined by the extension of the straight lines to the line, $\frac{p\,V_s}{V} = 0$.

The fact that the value of K in this situation is approximately unity is of interest in connection with the plotting shown in Fig. 12. In this curve the value of K, computed from the data obtained by Miss Blatch, is plotted as a function of the quantity $\frac{p\,V_s}{V}$. The most notable feature of this plotting is the apparent existence of a maximum value of K at a value of V which gives a minimum of the energy gradient for a given mixture in the pipe. Also, it is apparent that as the velocity decreases $\left(\frac{p\,V_s}{V}\text{ increases}\right)$, the value of K decreases and may well approach 1.

Fig. 13 contains parts of data supplied by Miss Blatch, and parts by Mr. Howard, plotted in the manner used in Fig. 11 for the data obtained at Climax. It is clear that in the ranges of variables covered in these plottings K is not unity, whereas it did have a value of practically unity for the data obtained at Climax.

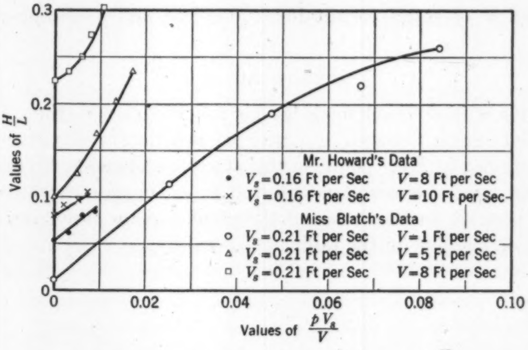

FIG. 13.—ENERGY GRADIENT AS A FUNCTION OF $\frac{p\,V_s}{V}$

Although adequate data are not available to make a thorough investigation, a superficial examination of the data already cited and some other less complete and reliable data on flow in dredge pipe lines quoted by Miss Blatch[7] indicates that the value of K may decrease as the diameter of the pipe increases.

It is to be expected that the following dimensionless quantities would form a very minimum of parameters with which to describe the coefficient K:

---

[7] *Transactions*, Am. Soc. C. E., Vol. LVII, December, 1906, pp. 402 and 406.

Reynolds number, **R**; $\frac{V_s}{V}$; the ratio, $\frac{\text{mean diameter of particles}}{\text{diameter of pipe}}$; and percentage of solids (p). Obviously, extensive information is necessary to determine experimentally the laws of the variation of K.

SUMMARY

The fundamental assumption of this study is that the energy, expended in maintaining the flow of a suspension of solids in a liquid, may be expressed as the sum of the energy required to maintain the flow of a homogeneous liquid of the same density, and the energy required to maintain the solids in suspension, through the mechanism of the fluid turbulence overcoming their tendency to settle.

The equations developed on the basis of this assumption lead to conclusions concerning the general features of the flow which are in good accord with the observed facts.

The unique flow observed in the tailings disposal line at Climax is adequately explained in a qualitative manner and certain features of the flow are analyzed quantitatively with good agreement between theory and observation.

In all cases in which complete data are available, and the variation of the coefficient K is not a factor, good agreement is found between theory and observation.

Additional experimental work in which all variables are carefully controlled and observed is essential to obtain a complete understanding of this type of flow.

ACKNOWLEDGMENT

The writer wishes to acknowledge his indebtedness to the officials of the Climax Molybdenum Company for their cooperation in permitting the use of the data, obtained at their plant, in this study. Particular thanks are due to C. J. Abrams, general superintendent, and E. J. Duggan, mill superintendent, for making possible an inspection of the plant and for supplying the detailed information on the flow in the tailings disposal line.

DISCUSSION

Arthur L. Collins,[8] Assoc. M. Am. Soc. C. E.—A system of measurement has been developed by the writer that is an aid in the solution of some of the important problems encountered in dredge operation. Several measuring units make up the system and are described as follows:

Velocity and Load Meter.—A section of the discharge pipe line can be made to serve as a meter. This requires a horizontal section of discharge pipe, 35 to 50 ft long, to which is attached a chart-recording, differential gage. The drop in pressure due to the resistance to flow generally will be about 20 in. of water pressure, or 0.75 lb per sq in.

As the fluid from the pump passes this section, three stages of flow resistance are recorded: First is the clear-water velocity; and second is the increase in the pressure drop due to the heavier fluid, which may be as great as 50% when the dredge is digging. The third stage may be considered a phenomenon. The pressure drop may increase suddenly as much as 100%, which indicates that there has been some marked change in the distribution of the solids in the fluid.

The records from the so-called load chart obtained from the meter section are supplemented by a gadget that is attached to the end of the pipe line. The object here is to determine how constant the pipe-line velocity is in value. This can be accomplished by the use of a revolving shaft to which are attached steel spokes with vanes on the ends. The vanes dip into the stream flow and provide a displacement record of velocity. The principal purpose of this gage is to obtain relative values. Thus, over a 60-min period the load-meter record, when synchronized with the end of the pipe record, will indicate how the pump responds to the load, in so far as maintaining a continuous velocity is concerned.

In dredge-pump operation it is desirable to use a pump that will maintain a constant pipe-line velocity regardless of the load. If the pump cannot maintain a fairly constant velocity, but varies several per cent and has a tendency to slow down under load, it cannot maintain its maximum output continuously.

Tests on small pumps pumping sand under laboratory conditions have led investigators to make broad statements regarding the operating characteristics of a dredge pump. Conventional velocity diagrams, which are purely assumptions, are used to account for variations in pump performance when pumping solids.

Other conditions that have their effect on pump characteristics should be mentioned. The fluid enters the eye of the pump runner at a high velocity and must make a right-angle turn to follow the passages in the pump runner. An additional loss of energy is concealed here that is probably more effective in altering the pump characteristics than the explanation given by the velocity diagram (see Fig. 4).

Slippage in a dredge pump means to the practical dredge operator a spinning of the runner that results in a decreased discharge. The peripheral speed of the pump runner is generally so high that the fluid leaves the runner nearly in a tangential direction. Conditions apparently arise in which the fluid revolves in the case and will not respond to the load pickup. This is another factor that must be taken into consideration in analyzing dredge pumps.

---

[8] Cons. Engr., Berkeley, Calif.

Thus, it must be realized that dredge pumps vary greatly in design. So many conditions enter into the final characteristics of the pump that field tests must be made on each dredge to determine how it can be operated at its best efficiency.

Another gage that is very important to this system of measurement has not been mentioned. This is a depth gage which is attached to the cutter and records on a chart the travel of the cutter. This chart, when synchronized with the load chart, indicates the load that is constantly being picked up by the suction pipe. Each cut or ledge can be rated in terms of load percentage. Thus, the difference in pickup between the port and starboard swings, as well as the shallow and deep cuts, is definitely known.

The following data were obtained from a load chart. It is for the duration of one dredge setup or step:

Cut No.	Time	Load by weight
1	11:30 to 11:37 a.m.	Load is 46.5% starboard swing
2	11:37 to 11:45 a.m.	Load is 21% port swing
3	11:45 to 11:52 a.m.	Load is 25.5% starboard swing
4	11:52 to 12:00 Noon	Load is 9% port swing
5	12:00 to 12:07 p.m.	Load is 23% starboard swing
6	12:07 to 12:17 p.m.	Load is 14% port swing
7–8	12:17 to 12:33 p.m.	Load is in the 3d stage

This overload occurs at the finish of the setup. It is to be noted that the peak pickup amounted to 46.5%, whereas the average is only 23%. Obviously, it should be possible to improve the cutter conditions, the design of the pump, and the method of operating the dredge, and thus increase the output materially.

The chief improvement in dredge operations will not be accomplished by work done in the laboratory on small pumps but by making the large dredge unit a laboratory in itself and recording the various operations.

Tests to determine pipe-flow coefficients fail to take into consideration one important factor that undoubtedly helps to maintain a high percentage of solids in suspension. A large number of discharge lines are made with 15.5-ft sections of pipe with slip joints. The tapered section is 1 in. smaller in diameter than the pipe. Thus in a 24-in. pipe the fluid increases its velocity by 8% at each joint. This has a nozzle effect that diffuses the solids. Even with this restricted area, the pipe coefficient may be as high as 130, using the Hazen and Williams tables.

On the other hand, a smaller pipe (say 15 in.) with long sections and rubber sleeves at the joints may have a coefficient of only 100. Excess friction should react directly upon the dredge output. If by using all the power available it is possible to maintain only 14 ft per sec, it should be possible to increase the output 25% by decreasing the frictional resistance and boosting the velocity to 17.5 ft per sec. In other words, the output will vary as the velocity. There is scarcely a dredge in operation that cannot be improved by applying better engineering technique.

H. A. Einstein,[9] Assoc. M. Am. Soc. C. E.—The problem of determining the pump and flow characteristics of a mixture of water and granular solids is of great practical importance. Only the abundance of difficulties involved may explain why so little research has been done and so few papers published in this special field. The numerous complications may also be the reason why the reports of earlier investigators failed to give full descriptions of all technique and apparatus. Both authors stress this fact but omit some information from their own reports. The writer misses especially a short description of the methods of making measurements.

In the pump test, it would be interesting and important to know if volumetric or venturi measurements were used for the discharge and how the two methods compare. For sufficiently fine particles, the venturi meter should give the correct discharge, if the pressure difference is measured by the height of a column of the mixture. For coarser particles, a relative movement of the particles against the water is to be expected in the venturi meter as well as in the pump. The solid particles will probably lag when the acceleration in the venturi meter occurs. Therefore, the water will be accelerated more than the total mixture as an average, and a slightly high manometer reading may be expected. Mr. Fairbank may be able to give some information about this point in his final discussion.

Another important measuring detail pertains to the lines between the taps in venturi, pipe, or pump, and the manometers or piezometer tubes. Part of these lines will be filled with a water-sand mixture, part with clear water. Are the points known at which this change occurs in each line? What correction for any differences in their level has been made? These questions are especially important for the measurement of the "hydraulic gradient *S*" in Table 3 of Professor Wilson's paper.

There is a simple device that can be used for measuring discharge for almost all flows through pipes. This device is the measuring elbow. Any elbow following a sufficient length of straight pipe can be used. The dynamic pressure in certain parts of the elbow seems to be extremely stable and therefore can be used for the measurement. The writer found that the point *b* (see Fig. 14), where the axis of the preceding straight pipe intersects the wall of the elbow, is very reliable. The difference in pressure between point *b* and a reference point *a* in front of the elbow is proportional to the velocity head $\frac{v^2}{2g}$ for wide ranges of velocities. For most normal elbows this coefficient seems to be close to unity. This principle of measuring can be used in almost every line of any size without additional energy loss, pro-

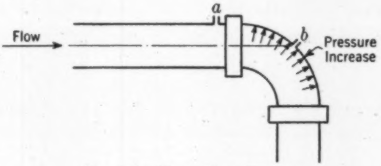

Fig. 14.—Measuring Elbow

---

[9] Hydr. Engr., SCS, U. S. Dept. of Agriculture, Greenville, S. C.

vided there is an elbow in the line. Here, too, a correction may be necessary for coarse sand in suspension.

Eq. 19 is the backbone of Professor Wilson's paper and, as such, perhaps is not sufficiently explained. It seems to be one of those hydraulic rules that simply add energy losses without regard to their interdependence. Its first term represents the amount of mechanical energy dissipated in a flow without the solids. The second term is the amount of turbulence energy dissipated by lifting the solid particles. The two terms, therefore, originate in two altogether different phases of the problem. The same energy may appear in the first term as mechanical energy being transformed into turbulence, and again in the second term, when this same turbulence is dissipated in lifting particles. The measurements themselves seem to indicate this tendency. The scatter of the points of Fig. 11 is considerable, but, still, some groups of points (series 1, runs 1–6; series 1, runs 8–13; and series 2, runs 1–7) unmistakably follow a slope of less than 45°. According to Eq. 19, this can be explained only as an efficiency above 100%, which is impossible. The writer's own experiments, therefore, seem to indicate that Eq. 19 does not explain the problem, even if it does seem to describe it satisfactorily.

Professor Wilson is definitely correct when he calls the criterion for settling of the sediment on the bottom of the pipe "a bed-load problem." It is definitely to be solved as a problem of the stability of this deposit. Unfortunately, present knowledge about bed load does not include any flows that could be compared with the flow in one of these pipes. Therefore, caution must be used when data from rivers are applied to pipes. However, if all the necessary information were available, these and similar pipe measurements could very well give exceedingly important information pertinent to certain bed-load problems. However, at least one series of measurements with 100% open cross section should be included, and, as stated previously, the measurements themselves should be described in more detail.

Both papers of this Symposium will prove to be very helpful to the engineer who must design apparatus for pumping solids in suspension. They provide him with some necessary information in a convenient and sufficiently accurate form.

H. E. Babbitt,[10] M. Am. Soc. C. E., and D. H. Caldwell,[11] Esq.—The contribution of Professor Wilson to the knowledge of the flow of solids in suspension is of value in providing information applicable to the turbulent flow of settleable solids suspended in water flowing in a circular pipe. The analysis is applicable to the condition of turbulent flow in which the relation between the settling velocity (V_s) of the suspended particles and the transporting velocity (V) of flow is appreciable in terms of the head loss $\left(\frac{H}{L}\right)$. Professor Wilson clearly states that his analysis is limited to the consideration of the transportation of noncolloidal, inert solids for which the average velocity of settling relative to the transporting liquid is known. It is apparent that the analysis is limited to mixtures in which the concentration of suspended solids is insufficient to allow mutual contact between the particles in such a manner that stress may be transmitted through the mixture. It is to be noted that the analysis does not supply information concerning the velocity required to maintain the particles in suspension; nor, from the information given, would it be possible to determine the head losses due to friction for the flow of any given mixture of solids and water.

---

[10] Prof., San. Eng., Univ. of Illinois, Urbana, Ill.

[11] Instructor, Civ. Eng., Univ. of Illinois, Urbana, Ill.

Information given by the writers[12] in 1939 and 1940 supplements that given by Professor Wilson. Laminar flow and turbulent flow of sludges in circular pipes were discussed, and a method was given for computing head losses due to the flow, in a circular pipe, of mixtures of solids and dispersion fluids through which stress may be transmitted. The writers' analysis covers the transportation of solids through circular conduits under conditions in which the settling velocity, V_s, of the suspended particles is negligible with respect to the transporting velocity.

If there is sufficient concentration of suspended particles to permit the transfer of stress, the mixture is said to have a yield value. This is defined as the shearing stress (τ_y) of the mixture, at which flow is impending. High concentrations of suspended particles commonly have a yield value. The existence of a yield value causes the mixture flowing in a pipe to exhibit a pseudoviscosity, higher than the viscosity of the liquid in which the particles are suspended, but decreasing as the velocity in laminar flow increases. A result is that the mixture moves in laminar flow in much the same manner as a very viscous liquid except that, in the case of the mixture, there is a moving plug of material in the center of the pipe and within which there is no movement between adjacent particles. The writers have shown that the velocity, V_c, at which so-called "plug flow," plastic flow, or laminar flow breaks into turbulent flow, is given by the expression

$$V_c = \frac{32\,\eta + 32\sqrt{\eta^2 + \dfrac{f\,\tau_y\,\rho\,D^2\,g}{0.96}}}{f\,\rho\,D} \quad \ldots\ldots\ldots\ldots\ldots (26)$$

in which η = coefficient of rigidity of mixture, in pounds per foot-second; f = friction factor in the expression

$$H = f\,\frac{L}{D}\,\frac{V^2}{2\,g} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots (27)$$

τ_y = shearing stress at the yield point of a plastic material, called yield value, in pounds per square foot; ρ = density of flowing substance, in pounds per cubic foot; and H = difference in static head between two points in a pipe, measured or expressed in feet of the flowing mixture. Hence, when V is less than V_c, Professor Wilson's analysis cannot be expected to apply.

An analysis of the experimental data reported by the writers, particularly for a Tennessee ball clay slurry, shows that the values of V_c lie between 2.0 and 15 ft per sec. The rate of settling of this material was of the order of 2 to 3 in. per day. Hence, at the velocity of 2 ft per sec (the lowest at which turbulence occurred in the writers' tests), the influence of the term $\frac{K\,p\,V_s}{V}$, shown in Eq. 19, on the friction loss, was negligible when compared with the term $\frac{f\,V^2}{2\,g\,D}$.

---

[12] "Laminar Flow of Sludges in Pipes, with Special Reference to Sewage Sludge," by H. E. Babbitt and D. H. Caldwell, *Bulletin No. 319*, Eng. Experiment Station, Univ. of Illinois, Urbana, 1939; also "Turbulent Flow of Sludges in Pipes," by the same authors, *Bulletin No. 323*, *ibid.*, 1940.

When the velocity of flow is greater than V_c, the friction loss due to the flow of a slurry, through a circular pipe, will be the same as the friction loss for the flow, through a circular pipe, of a liquid with the same viscosity as the dispersion medium of the mixture. Hence, in the case of suspensions of solid particles in water, the common hydraulic formulas can be used. This implies that for such a suspension the conditions of flow in a circular pipe can be expressed as

$$\frac{H}{L} = \frac{f\,V^2}{2\,g\,D} \qquad (28)$$

This agrees with Professor Wilson's conclusion. It should be emphasized again that Eq. 28 is applicable only to turbulent flow at a velocity high enough to maintain the particles in suspension.

Importance should be attached to the limiting concentration of suspended matter above which a yield value appears. It is only by differentiating the regions of solids concentration above and below the existence of a yield point that confusion may be avoided. When the concentration of suspended particles is sufficiently low to show little or no yield value in the mixture, when the term $\frac{K\,p\,V_s}{V}$ (Eq. 19) becomes appreciable with respect to the term $\frac{f\,V^2}{2\,g\,D}$, when the flow remains turbulent, and when particles remain in suspension, Professor Wilson's analysis will prove of most value.

Warren E. Wilson,[13] Assoc. M. Am. Soc. C. E.—The comments of those who have discussed this paper have been most helpful. An effort will be made herein to clarify certain details.

Mr. Einstein describes the difficulties inherent in measuring head losses in pipe lines carrying solids in suspension, and notes that the method of measuring the hydraulic gradient S in Table 3 was not described. These measurements were made by the staff of the Climax Molybdenum Company and it is the writer's understanding that the hydraulic gradient was determined by observing the difference in elevation between the surface of the liquid-solid mixture in the stand-pipe and the outfall of the pipe. It is apparent that this method embodies the measurement of the length of a column of liquid-solid mixture which would have an average density equal to that of the flowing mixture.

As was stated by Mr. Einstein, Eq. 19 is the underlying feature of the discussion. To clarify and elaborate upon the concept involved, and to correct an error, the equation might be rewritten in the form:

$$\frac{H}{L} = \frac{f\,V^2}{2\,g\,D} + \frac{w_s - w}{w_s}\left[\frac{C_1\,p\,V_s}{V} + \frac{p\,V_s}{V}\right] \qquad (29)$$

in which the terms have the following significance:

---

[13] Prof. and Head, Dept. of Mechanics, Colorado School of Mines, Golden, Colo.

The term $\frac{f V^2}{2 g D}$ represents the energy per pound of fluid per unit length of pipe that would be dissipated in the turbulent flow of a homogeneous fluid. The term $\frac{C_1 p V_s}{V}$ represents the energy per pound of mixture per unit length of pipe, in excess of, or less than, that which would be dissipated in turbulent action by the homogeneous fluid due to the presence of the solids in suspension. The term $\frac{p V_s}{V}$ represents the energy per pound of fluid per unit length of pipe dissipated by the settling of the solids. The factor $\frac{w_s - w}{w}$ (in which w_s is the weight per unit volume of the solid material and w is the weight per unit volume of the mixture) is necessary to take into consideration the fact that the change in potential energy of the solids is a function of the effective weight of the immersed solids and not of the unit weight w_s alone. This consideration requires that Eq. 15 be written as follows:

$$\frac{w}{w_s} K\, p\, A\, L\, V_s\, T\, (w_s - w) = w\, h_1\, A\, L$$

and all equations derived therefrom should be revised accordingly. However to simplify the situation all that is necessary is to consider that the original equations are to be used only in discussing the flow of sand of specific gravity 2.65. The factor K may then be considered to include the factor $\frac{w_s - w}{w_s}$.

Now Eq. 19 is equivalent to Eq. 29 if one writes

$$K = (1 + C_1) \qquad (30)$$

The value of K therefore depends upon the value of C_1 and may be either greater or less than unity, depending upon the sign and magnitude of C_1.

Negative values of C_1 apparently exist in pipe flow as may be deduced from Fig. 9 in which the energy gradient for flows with solids dips below that for flow without solids, implying a negative value of C_1 greater in magnitude than unity. Similar evidence exists in certain data on open channel flow investigated by the writer,[14] in which flows of solid-water mixtures with gradients less than the expected gradient for pure water are found.

That such a condition is possible may be shown analytically in a qualitative manner by considering the elementary equation for shear stress in a liquid-solid mixture based on the momentum exchange concept, thus

$$\tau = \epsilon \frac{d}{dy} (\rho_m u) = \epsilon \rho_m \frac{du}{dy} + \epsilon u \frac{d\rho_m}{dy} \qquad (31)$$

in which ϵ is the so-called "austausch" coefficient, ρ_m is the local density of the mixture, u is the local velocity in the direction of mean flow, and τ is the shear stress.

---

[14] "Transportation of Debris by Running Water," by G. K. Gilbert, *Professional Paper No. 86*, U. S. Geological Survey, 1914.

The quantity $\frac{d\rho_m}{dy}$ is negative since the density of the mixture necessarily decreases as the distance y from the channel bottom decreases. Hence the shear stress τ may be either less or greater than that for clear water under similar circumstances, and the resulting distribution of velocity may give either a lesser or greater flow than for clear water under like conditions.

Professor Babbitt and Mr. Caldwell clearly define the limits of the applicability of the writer's analysis and their equation for the critical velocity defining "plug flow."

It is true that the present analysis does not yield a result which will predict, directly, either the minimum velocity for transporting solids or the head loss to be expected under given conditions. It is hoped that further treatment of the problem, both experimentally and by theoretical analysis, may yield useful results in predicting these two vital factors.

Elaboration of this elementary attack on the problem has yielded some interesting results in the problem of open channel flow of solids in suspension but requires further work to yield more than semi-empirical results.

DESIGN AND CONSTRUCTION OF SAN GABRIEL DAM NO. 1

By Paul Baumann,[1] M. Am. Soc. C. E.

With Discussion by Messrs. E. Soucek, William P. Creager, Joseph Jacobs, Jacob Feld, Walter L. Huber, Federico Barona, G. H. Hickox, and Paul Baumann.

Synopsis

Dam sites distinctly favorable for masonry structures, particularly of the massive type, are rapidly being exhausted the world over. Hence, engineers are faced, more and more, with the problem of design and construction of safe and economical dams for dam sites far from ideal, relative to topography, geology, and geography. The latter is particularly important with regard to earthquake belts, such as are well established, and to the latitude and elevation at which the dam is to be located.

In the design and construction of the San Gabriel Dam No. 1 in California, it was necessary to consider all of these features. The solution of the problems thereby encountered, and particularly the one connected with stability and watertightness during major earthquakes, is believed to be novel. For the dam proper it expresses itself in the combination of compacted earth with loose rock—and particularly with compacted rock (that is, with artificial stone). The manufacturing methods of the latter and its physical qualities established by tests prior to, and during, construction are believed to be of special interest. Hence this paper treats this subject in particular detail. It also deals with features of special interests, incorporated in appurtenant works.

Introduction

The 4,000 sq miles of surface area of Los Angeles County, California, may be divided into four principal sub-areas from a standpoint of flood control: Mountain area (catchment, erosion) with 1,500 sq miles; foothill area (debris cones) with 500 sq miles; valley area (inundation) with 1,700 sq miles; and desert (arid) occupying the remainder.

Note.—Published in September, 1941, *Proceedings*.

[1] Senior Asst. Chf. Engr., Los Angeles County Flood Control Dist., Los Angeles, Calif.

The San Gabriel Mountains form the principal range and the San Gabriel River is its principal drain. Its drainage area includes 220 sq miles above the mouth of the canyon with a maximum range in elevation of nearly 10,000 ft.

Particularly interesting is the nearly straight alinement of the two main forks, east and west, which approach each other in opposite directions and the confluence of which is a distinct landmark known as "The Fork."

San Gabriel Dam No. 1 is located approximately 2¼ miles downstream from the Fork. It is the principal one of an originally proposed system of three dams, two of which (Dam No. 2 and Dam No. 3) were to control the West and East Forks, respectively. Although Dam No. 2 on the West Fork was completed in the spring of 1935, Dam No. 3 on the East Fork was abandoned for reasons of economy.

The Original Design

In order to comprehend, fully, the revised or final design of Dam No. 1 as constructed, it is necessary to refer back to the original design that was prepared by the Los Angeles County Flood Control District prior to 1933 when the original contract was let.

The original design called for a rock-fill dam chiefly consisting of large, hard, and strong rock with voids of corresponding size. This rock was to be placed dry—that is, without the aid of sluicing water. The dam was to be provided with a laminated, shotcrete water slab with a substantial layer of packed rock directly beneath.

The rock was to be produced by approved methods in what is known as Quarry 10 which is located approximately one-half mile downstream of the dam site (described subsequently in connection with Fig. 28). It is a cut in a ridge with its floor at El. 1390 and an average slope of 1 to 1. It consists chiefly of a granitic diorite, sheared and crushed due to faulting and crossed by numerous intrusions of varying magnitude and composition. The quantity, quality, and size of the quarried rock was specified for the various parts of the dam.

In the spring of 1933 the work was started under contract. After excavation of the stream-bed material down to bedrock and the construction of a section of the cutoff wall along the base of the upstream contact, the placing of the rock fill in the excavated stream bed was started.

For the purpose of producing the rock to be placed in the fill, the specifications provided for the elimination of fines and spalls by means of a screen, commonly known as a "grizzly" in western construction parlance. This "grizzly" had clear slot openings of 6 in. The material passing through these openings was wasted, and the material passing over was acceptable for the fill, provided it satisfied the requirements regarding weight, strength, and soundness.

However, as the quarrying of rock progressed, it became quite evident that rock, satisfying the specifications, could not be produced economically in sufficient quantity in that for each acceptable cubic yard approximately three had to be wasted. Under the contract the waste had to be paid for at 40¢ per cu yd or 53⅓% of the acceptable rock and the waste had been estimated at less than one third of the latter. It was obvious, therefore, that completion of the dam inside the estimated cost was out of the question. Consequently, construction was suspended in October, 1934, at which time some 450,000 cu yd out of an estimated total of 5,562,000 had been placed in the dam and studies for a revised design were commenced.

The original design had been approved by consulting engineers and geologists of national repute.

The Revised Design

The Dam Proper.—The knowledge regarding relative quantities and characteristics of the rock, gained during quarry operations, led to the conclusion that the design of a feasible dam would have to include the material originally classed as waste—that is, principally the material passing through the "grizzly" openings. Hence, in principle it was necessary to adapt the design to existing conditions, which conditions, in turn, called for a change in the design from a true or homogeneous rock-fill type with a small, unavoidable percentage of fines to a mixed or heterogeneous rock-fill type with a large and, in fact, predominant percentage of fines. Hence, it called for a change to a type of fill whose physical characteristics (particularly in relation to stability and permeability) were of a radically different nature from the original type. This recognition was given further emphasis through the indispensable requirements regarding earthquake resistance of major structures in California.

The inclusion of a large percentage of fines in the fill naturally called for the flattening of the upstream and downstream slopes relative to the original design. Clearly, this requirement was primarily governed by the behavior of such a fill when saturated, particularly when under the influence of lateral mass forces in addition to gravitational forces during earthquakes. The open-type rock fill, as originally designed, was not subject to saturation above the stream bed and hence was not affected by this important phenomenon.

The flattening of the slopes as well as experience gained during the construction of San Gabriel Dam No. 2 (which was of substantially identical design as to type as the original of Dam No. 1) called for a change in the watertight membrane. This change was encouraged by the discovery of a large deposit of clayey sand or loam of unusual uniformity approximately 1¾ miles upstream from the dam site. It was an old homestead, known as Persinger Flat, situated inside the reservoir area which the Los Angeles County Flood Control District had acquired. The character of this material suggested its use as a relatively thin, impervious layer or zone whose plasticity (and with it, flexibility) would be assured so long as it was protected against drying out. The intimate contact of this zone with the existing part of the cutoff wall, as well as with the ultimate extension of the cutoff wall, was naturally a pertinent feature. To enhance the sealing quality of this zone a 6-in. shotcrete blanket was provided along its contact area with bedrock. This was to prevent the intrusion of water along paths shorter than the full normal thickness of the zone. A watertight connection was provided between this blanket and the cutoff wall.

These studies in connection with the revised design were accompanied by extensive tests on the available rock material particularly for the purpose of establishing suitable methods of compaction or petrifaction of the waste material which, as previously outlined, formed the bulk of the quarried rock. The purposes of these tests were to establish:

(1) The maximum size of rock which, if embedded in finer material, could be rolled with standard sheepsfoot rollers;

(2) The necessary roller weight to produce adequate compaction;

(3) The necessary number of roller passes;

(4) The most favorable proportion between fines, defined as particles $\frac{1}{4}$-in. or less in size, and rock, defined as particles greater than $\frac{1}{4}$ in. in size;

(5) The breakdown of the rock;

(6) The moisture content of the fines which would lead to adequate compaction with least work;

(7) The permeability of the compacted fines;

(8) The plastic and the elastic volume changes of the compacted fines;

(9) The penetration pressure of plasticity needles for the compacted fines; and

(10) The shearing strength of the compacted fines and its relation to plasticity.

Previously, tests had been conducted on loose rock and further tests were now made on mixes of loose rock and fines for the purpose of establishing: (*a*) Settlement under load for dry and wet material; (*b*) breakdown under load; (*c*) change in unit weight due to settlement; and (*d*) permeability.

Figs. 1 and 2 show the revised design in plan and section. The cross section of the dam is divided into six zones as follows:

Zone 1, consisting of quarry-run material varying from very fine material next to Zone 2 to relatively coarse material at the upstream slope. This zone may be considered largely a protective zone.

Zone 2, consisting of a clayey sand compacted to a dry weight of at least 115 lb per cu ft.

Zone 3, which may be considered the backbone of the dam, or the core, consisting of quarry-run material having passed 6-in. by 9-in. "grizzly" openings, compacted by rolling and tamping to a dry weight of the fines (particles smaller than $\frac{1}{4}$ in. in size) of at least 120 lb per cu ft.

No gradation of material between the upstream and the downstream slope was proposed for either Zone 2 or 3.

Zone 4, consisting of loose quarry-run material with the finest material next to the downstream slope of Zone 3 and gradually becoming coarser and more porous toward the downstream end of Zone 4.

Zone 5, consisting of relatively large rock forming a free draining mass and a protection against erosion to the zone below.

Zone 6, consisting chiefly of rock originally placed in the stream-bed excavation and moved under the revised design into its new position. This rock is relatively hard.

A statical analysis of equilibrium was made of a theoretical maximum vertical dam section of unit width under the influence of simultaneous full hydrostatic water pressure and lateral mass forces due to earthquake. The latter are based on the acceleration of one tenth that due to gravitation—that is, on 0.1 g of the mass $\frac{V}{g}$ of the dam, as well as of the so-called body of inertia of water next to the dam.[2] The resultant force H of all horizontal loads was

assumed to be resisted along a horizontal plane at El. 1120, which coincides approximately with the bedrock level. Due to the protective rather than constructive nature of Zone 1 and the plastic condition of Zone 2 as previously described, no resistance was credited to Zone 1 and Zone 2. Hence, because of their mass and acceleration these zones acted entirely as a load.

The analysis shows a necessary average shear coefficient $\frac{H}{V}$ of 0.37. Test results outlined in the course of this paper will show this value to be well within the actual shearing strength of the critical material—namely, the saturated fines in Zone 3.

---

[2] *Transactions*, Am. Soc. C. E., Vol. 98 (1933), p. 418.

The safety against sliding due to shear is further enhanced by the configuration of the dam site (see Fig. 1).

THE ROCK AND SOIL TESTS

With few exceptions the physical tests on materials for the dam were conducted in the field, either in the laboratory or in the open. The latter principally included full-scale rolling and tamping tests for the purpose of establishing practical construction methods for Zones 2 and 3. Hence they differ from the relatively small-scale laboratory tests which served to establish the intrinsic properties of the materials by means of soil mechanics research. They will, therefore, be treated separately. The former fall into three basic groups—namely, those on rock only, those on rock and fines, and those on fines only.

FIG. 2.—COMPOSITE MAXIMUM

The first group of tests represents open rock fill, placed dry or wet, such as constituted the bulk of the original design and as was placed in the upstream extremity of Zone 1 and in all of Zones 5 and 6. The second group of tests represents a mixture of rock and fines, varying between "mostly rock" and "mostly fines," such as was placed in the greater part of Zone 1 and all of Zone 4. The third group of tests represents fine material such as was placed in Zone 2 and such as forms the governing part of Zone 3.

Whereas the first two groups principally served to establish relations between load and settlement as well as permeability of the loose material, the third group served to establish all of the pertinent properties of compacted sand and soil.

The discussion of all of the tests conducted in each group would require far more than the space available. Therefore, it will be limited to those, the results of which are believed to be typical.

First Group of Tests.—Tests to establish the settlement under load of representative rock samples were conducted in the field laboratory by means of cylinders. Two sets of three cylinders, each 24 in. and 30 in. in diameter and 24 in. and 30 in. high, respectively, were used. Pressures as great as 325 and

200 lb per sq in., respectively, could be applied by means of hydraulic jacks. Apparatus for the purpose of sluicing the rock was provided overhead. Samples of variable gradation of igneous rock were used.

Fig. 3 shows the test result of typical rock samples from Quarry 10. In Tables 1 and 2 test data are shown in detail.

The influence of sluicing, such as that due to a torrential rain, is evidenced in the sudden change in the settlement trend in Cylinders 2 and 3 upon the application of water. Cylinder 1 contained a sample from the Devil's Canyon Quarry which supplied the rock for Dam No. 2. It is a granitic gneiss of excellent quality. The corresponding results are shown in Table 1 for the purpose of comparison. They are omitted from Fig. 3.

SECTION, SAN GABRIEL DAM NO. 1

These tests combined with the experience gained during the construction of San Gabriel Dam No. 2 prompted the provision, in the revised specifications, for the application of approximately 2 cu yd of water to 1 cu yd of loose rock at the time of placing.

The breakdown due to the settlement under load (Table 2) is reflected in the screen analysis made at the end of the test as compared to the original one and particularly in the respective fineness moduli.

Second Group of Tests.—Samples used in these tests included fines varying between 20% and 60% by weight. Three 24-in. by 24-in. cylinders were used. The following tests are typical for this group:

A mixture of 80% rock and 20% fines was placed in Cylinder 1, 60% rock and 40% fines in Cylinder 2, and 40% rock and 60% fines in Cylinder 3. Uniform initial dry weight (placing density) was striven for. The cylinders were equipped with porous disks at the top and bottom of the sample to permit the passage of percolating water. A small initial vertical load was applied to balance the pressure due to water percolating in an upward direction until the rate of percolation had become constant.

The load was then increased in steps of 25 lb per sq in. until an ultimate load of 325 lb per sq in. was reached. Before the application of each load increment, movements due to settlement had diminished to negligible values. The total settlement and the rate of percolation were observed for each load

increment. As indicated by the heavy line in Fig. 4(*a*), a mixture of 55% rock and 45% fines would tend to show minimum settlement. Percolation rates are shown in Fig. 4(*b*).

Thus far no attempt had been made to ascertain the effect on the settlement of "arching" of the material in the cylinders. For this purpose the bottoms of two of the three 24-in. by 24-in. cylinders (Cylinders 1 and 3) were separated from the base plate by means of set screws and wedges, respectively. The perforated disks supporting the material were blocked up about 6 in. from the base plates to make ample allowance for the settlement of these cylinders. Cylinder 2 was set up as before; that is, it rested directly on the base plate.

A mixture of approximately 65% rock and 35% fines was placed as uniformly as possible in each of the three cylinders with the aid of sluicing. The top disks were then placed and a vertical load applied in 25 lb per sq in. increments to a maximum of 325 lb per sq in. as before. Percolation of water through the samples was not practicable because of the separation of two of the cylinders from the base and consequent lack of a water seal.

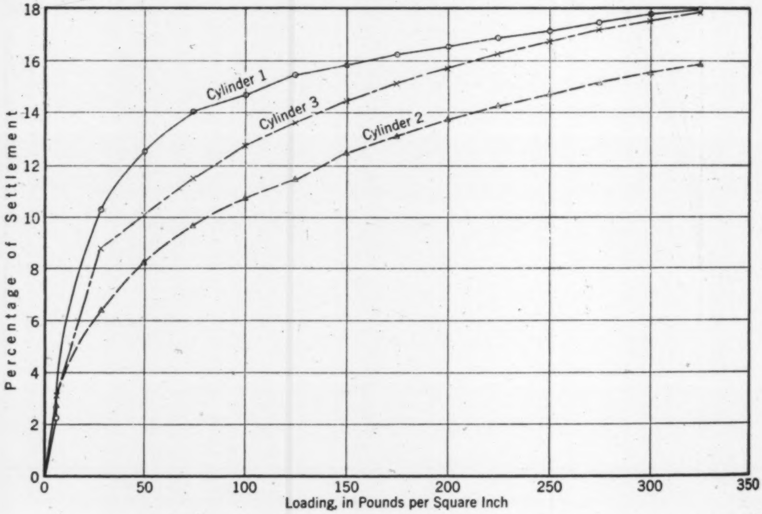

FIG. 5.—ARCHING EFFECTS, SECOND GROUP OF TESTS

Immediately after the application of the initial load of 25 lb per sq in., Cylinders 1 and 3 were completely freed from base support by raising the set screws and removing the wedges, respectively. Hence the cylinders were supported by friction between their inner surface and material only.

The result of this test is shown in Fig. 5. It shows that with cylinders of these dimensions arching is an important factor. It is expressed through the excess in settlement of the material in Cylinders 3, and particularly Cylinder 1 relative to Cylinder 2. The set screws served to raise Cylinder 1 slightly before each load increment. Furthermore, the cylinder walls were tapped. Arching to the walls was thereby not only reduced but substantially eliminated. Fineness moduli resulting from these tests are given in Table 3.

TABLE 3.—FINENESS MODULI, SAMPLES TESTED FOR ARCHING EFFECT

Description	CYLINDER 1		CYLINDER 2		CYLINDER 3	
	Before	After	Before	After	Before	After
Percentage of fines	35.3	43.1	35.3	43.0	35.9	39.9
Fineness moduli	6.01	5.61	6.01	5.68	5.96	5.82

Before proceeding with the third group of tests (which is concerned with the fines only), the field tests will be discussed.

The Rolling Tests.—The average quarry material, passing either over or through the 6-in. by 9-in. "grizzly" openings showed a typical gradation based on dry screening, as shown in Table 4.

TABLE 4.—TYPICAL GRADATION OF QUARRY MATERIAL, BASED ON DRY SCREENING

Classification	Rock		Rock		Fines		Fines

[a] Passing over. [b] Passing through.

Hence the material, subject to compaction in Zone 3, contained an average of about 43% rock and 57% fines. Obviously the stability and permeability of such a fill are governed by the density of the fines. The latter, in turn, is governed by the breakdown of the rock due to compaction, because unless breakdown occurs, pressure is transmitted from rock to rock through point contact and relatively little pressure is transmitted by fines in the interstices.

Test fills of quarry materials, having passed through "grizzlies" with openings varying from 3 in. by 9 in. to 6 in. by 9 in. in the clear were placed in 9-in. to 12-in. layers and compacted by means of a single-drum sheepsfoot roller. The drum was 58 in. long and 42 in. in diameter. It had eighty teeth and feet, each 8 in. long, and a bearing area for the feet of approximately 8 sq in. The weight of the roller was varied between 4.75 and 12.1 tons by filling the drum with suitable materials. A total of twenty-four test fills were rolled, each about 80 ft long, 12 ft wide, and 3 ft high. The test fills were divided into four sections, *A*, *B*, *C*, and *D*, roughly 12 ft by 20 ft. Six layers were spread, between 9 in. and 12 in. thick, and compacted by means of from ten to forty roller passes. The moisture content was varied between the four sections in intervals of approximately 2%—namely 7%, 9%, 11% and 13% more or less. Immediately after completion of each fill, twelve samples were taken (three from each section) to ascertain the degree of compaction. For this purpose a shallow pit about 4 ft by 4 ft in size was first dug to remove the top layer and its floor leveled off. A metal ring 12 in. in diameter was then set and plaster of Paris placed around it. A hole or pocket was then dug within the ring by suitable hand tools and the excavated materials placed in a can, sealed, and weighed. The volume of the hole was determined by filling it with fine, dry beach sand of known unit weight. The unit weight, inclusive of moisture, of the compacted fill was thereby established.

Next, the rock was separated from the fines by means of a No. 4 screen, spread out on burlap, dried, and weighed. Its apparent specific gravity and volume were then determined through immersion. Subtracting the rock volume from the total volume gave the volume of fines. After determining the average moisture content of the latter, the dry density of the fines resulted. The dry density served as the criterion of compaction as it proved to be the governing factor in determining the intrinsic properties of the fill.

For one and the same roller weight and number of passes, the dry density of the fines was principally governed by: The relative hardness, the percentage of rock, and the moisture content. The respective typical gradation before and after rolling is shown in Fig. 6. The breakdown due to rolling is evident.

Based on the rolling tests and particularly on the screen analyses before and after rolling, a relation between roller weight and breakdown of the average quarry rock was obtained. This is shown in Fig. 7. It is based on equal percentages of fines; that is, 40% ± before rolling. Guided by this result, the District proceeded with the design and construction of five double-drum roller units as shown in Fig. 8 and one single-drum unit. The dead weight of each double-drum unit was 14.50 tons and averaged 24.75 tons, or 12.375 tons per drum when filled with saturated sand.

TABLE 5.—TEST LOADS IN TONS TO DETERMINE ECONOMICAL SIZE OF ROLLERS

Load	ROLLER UNIT[a]			
	D_1	D_2	D_3	S_1
Unloaded	14.50	14.50	14.50	7.00
Water loaded	19.00	19.25	17.25	9.25
Water and sand loaded	25.50	24.25	24.50	11.00

[a] D = double drum and S = single drum.

Studies were made to ascertain the most economical combination of rollers that would satisfy the requirements regarding the compaction of the material in Zone 3. They were accompanied by tests. Three double-drum units and one single-drum unit were used unloaded, partly loaded and fully loaded, with weights in each case as given in Table 5.

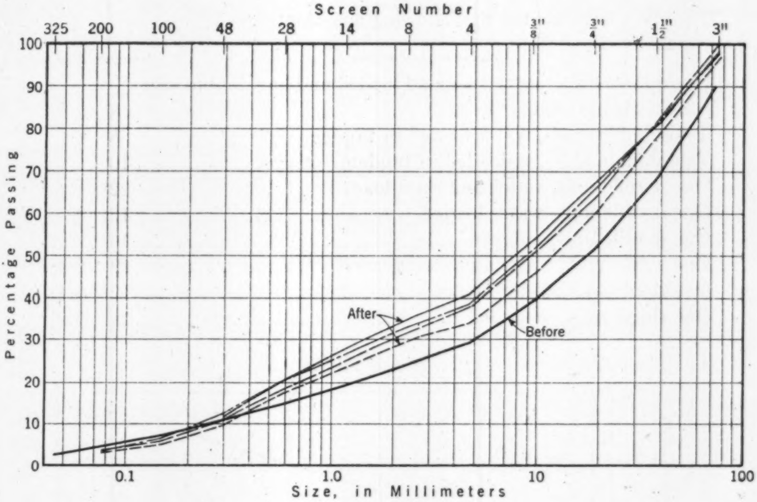

FIG. 6.—GRADATION OF ROCK FROM QUARRY 10, BEFORE AND AFTER ROLLING

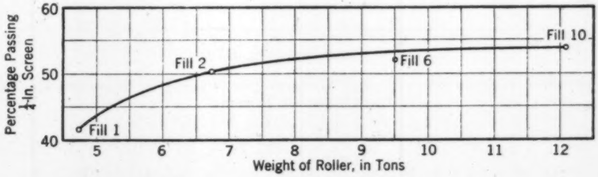

FIG. 7.—BREAKDOWN DUE TO ROLLING

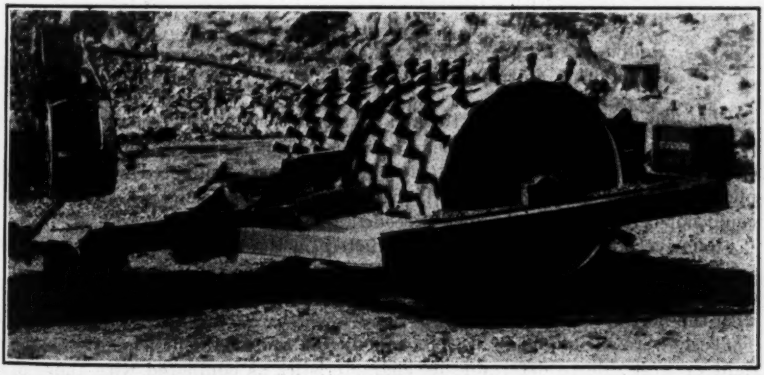

FIG. 8.—TWO-DRUM SHEEPSFOOT ROLLER

The rollers were used in the following combinations:

Combination of rollers	Number of passes	
One double unit, water and sand loaded and one double unit unloaded in tandem	8	
Two double units, water loaded in tandem	8	
Two double units, unloaded in tandem	10	
One double unit, water and sand loaded	12	
One double unit, water loaded	12	
One double unit, unloaded	16	
One single unit, water and sand loaded	12	(24)
One single unit, water loaded	12	(24)
One single unit, unloaded	16	(32)

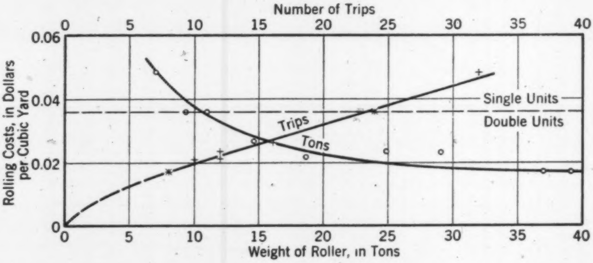

FIG. 9.—RELATION BETWEEN ROLLER WEIGHTS AND NUMBER OF TRIPS FOR CERTAIN UNIT COSTS OF ROLLING

The result is shown in Fig. 9. The field cost, without overhead, in dollars per cubic yard of rolled materials, is based on the following charges:

Equipment	Rate, in dollars per hour
One tractor with bulldozer	3.75
Tractor operator	0.8625
Double-drum unit roller	0.50
Single-drum unit roller	0.30

The Tamping Tests.—Next to the abutments a strip, 2 ft to 3 ft wide, had to be compacted by means of hand tampers because the rollers could not operate there. For this purpose, tamping tests were conducted with electric, pneumatic, and gasoline tools. It was found that satisfactory compaction could not be obtained if the rock exceeded about 40%.

Relatively few field tests were conducted on the material in Zone 2. Its typical characteristics are reflected in Figs. 10, 11, and 12, showing wet and dry screen analyses and compaction data. This material compared favorably with the best of the soil on record.

Tests were also made on samples taken from the abutments, mainly on the right or west side to determine its characteristics as compared with those of the materials in Zone 2 and Zone 3. It was found that even the softest of rock encountered after stripping showed dry densities and corresponding stability and permeability which were at least as satisfactory as those pertaining to the fines in Zone 3.

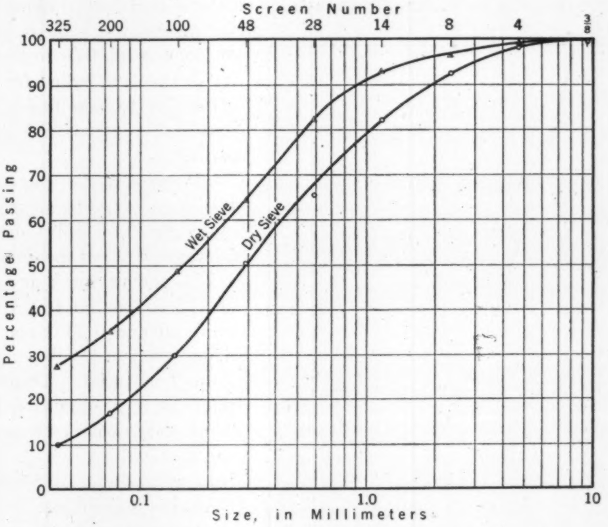

FIG. 10.—SIEVE ANALYSIS OF COMPOSITE SAMPLE, ZONE 2

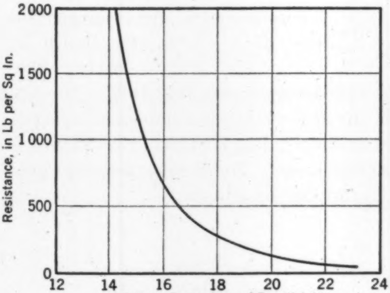

FIG. 11.—PLASTICITY-NEEDLE PENETRATION RESISTANCE; ZONE 2

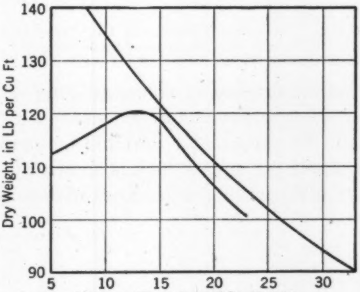

FIG. 12.—DRY WEIGHT; ZONE 2

Samples from the natural stream bed taken at various depths and distances downstream from the proposed toe of Zone 3 showed satisfactory stability and permeability under surcharge. The latter had to be such as to freely drain the flow due to percolation through the dam on the assumption of a full reservoir for an indefinite period of time.

The Third Group of Tests

All of these tests were conducted in the laboratory. They served to determine the intrinsic properties of the fines in Zone 2, and particularly in Zone 3, and hence were the most significant tests, from the standpoint of experimental soil mechanics. The importance of Zone 3 relative to the stability of the dam called for special attention to the fines of that material, particularly when saturated.

Permeability.—Percolation tests, conducted by means of 8-in. cylinders (fines only) showed an average rate of percolation of 1.5 ft per yr for a dry density of 125 lb per cu ft for Zone 3 material and 0.50 ft per yr for a dry density of 116 lb per cu ft for Zone 2 material. These values refer to a gradient of 1 on 1. They were obtained by reducing the test values, which resulted from a gradient of 80 on 1, in the same proportion.

Percolation tests conducted on composite and mixed materials of Zone 3 in the 24-in. cylinders substantially confirmed the results. They are shown in Fig. 13. They clearly reflect the importance of adequate compaction of the fines (see Fig. 13).

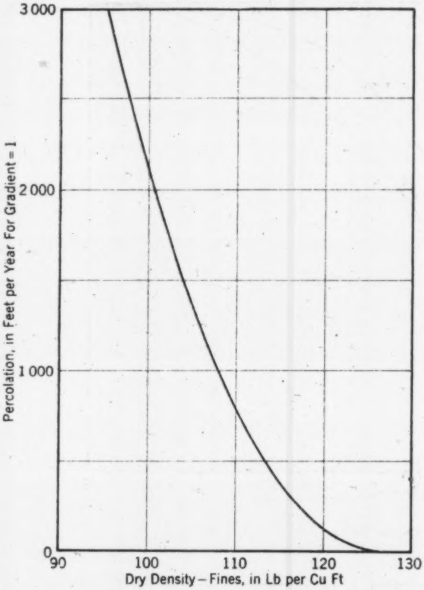

Fig. 13.—Relation Between Dry Density of Fines and Rate of Percolation

Compaction and Breakdown.—Fig. 14 shows the relation between compaction and breakdown for variable moisture contents. Isopenetration resistance in pounds per square inch is shown by broken lines. The results were obtained by compacting typical fines with a 5½ lb rammer as follows:

Curve (Fig. 14)	Number of drops	Force
A	5	4-in. drops
B	15	4-in. drops
C	15	Medium tamps
D	10	Hard tamps
E	25	Hard tamps

Shearing Strength.—The tests to establish the shearing strength of the saturated fines in Zone 3 led to results that are believed to be most significant so far as the intrinsic properties of this material are concerned. They were based on the fundamental concept that the shearing strength is the only criterion of safety of a saturated, granular mass in a dam fill in so far as structural stability is concerned, because, on the one hand, such a granular mass has no tensile strength and, on the other hand, it cannot fail due to compression as long as its lateral movement is restricted—that is, as long as it is confined. This material placed in a cylinder, for example, could be subjected to any pressure without the danger of failure, as long as the cylinder successfully resisted lateral pressure. Failure of the cylinder, however, would elimi-

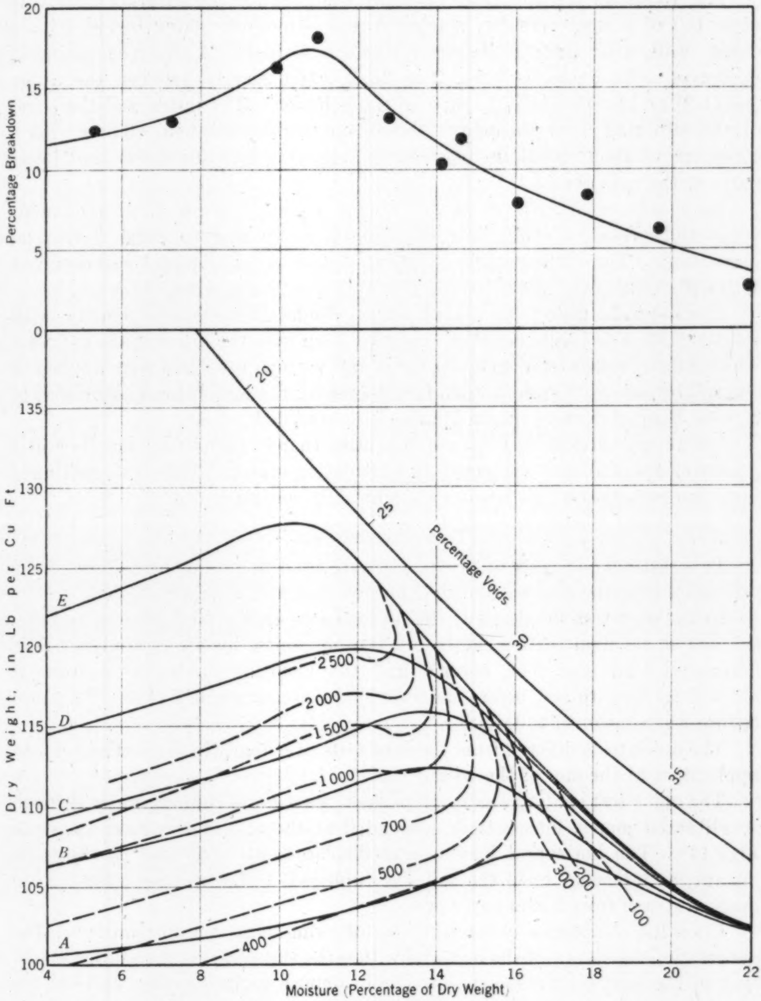

Fig. 14.—Compaction, Breakdown, and Penetration Resistance

nate the outer resistance to lateral pressure and would permit particles to move laterally and relative to each other unless restricted by internal friction; that is, by shearing strength.

Fig. 15 shows the apparatus specially designed for the shearing tests. It consisted of a steel cylinder, machined and chromium plated inside, with a 0.5-in. wall, 4 in. internal diameter, and 11 in. high. A slip ring (point 1) reinforced with a heavy band, 2 in. high, fitted snugly between the upper (point 2) and lower (point 3) parts of the cylinder. The inside and the edges of the slip ring were chromium plated and highly polished. There was a clearance of about 0.001 in. between the slip ring and the upper and lower parts of the cylinder.

By means of a counterbalanced (point 4) lever (point 5) arrangement, horizontal pressures could be exerted on the slip ring to cause horizontal movement. The ratio between vertical action and horizontal reaction was 1 : 14.40.

The soil to be tested was placed in the cylinder at the desired density, with the slip ring at its initial position—namely, flush with the inside of the cylinder. The material rested on a perforated seat and vertical pressures were applied to the soil by means of an hydraulic jack (point 6), the load being transmitted to the soil through a stem (point 7) and perforated disk.

Before any vertical load was applied (other than enough to balance the water pressure) the soil was subjected to percolating water. This was continued until the percolation rate became substantially constant.

Test Procedure

Two distinct methods of procedure were used in producing failure of the soil under shearing stress—namely, the slow test and the quick test.

In the slow test the desired vertical load was applied and allowed to bring the soil to its final settlement before the horizontal load was applied. The horizontal load was then applied and the resulting horizontal movement allowed to come to rest before the next load increment was added. This procedure was continued to failure.

The quick tests differed from the slow tests principally in the method of load application at the end of the lever.

The quick test loading was accomplished by means of running water through a calibrated meter, into a tank suspended at the end of the lever (point 5, Fig. 15). The horizontal loading and displacement were read at the same instant, at intervals, until the soil was ruptured. The time required for the quick test was from 2 min to 10 min.

Upon the completion of the test, the following data were obtained: (*a*) The penetration resistance of the material within the slip ring; (*b*) the moisture content of the soil; (*c*) the weight of soil, to determine its density, and (*d*) the specific gravity of the material, to determine the relative saturation of the soil under test conditions.

Soil Characteristics

Gradation.—Enough of typical Zone 3 material was secured to run all of the tests before they got under way in order that there would be no appreciable variation in the material to influence the results.

The soil used in the tests could be classed as silty sand. When wet the soil was more plastic than elastic. Periodic gradation analyses were made on the soil to check its variation as the series of tests progressed. The fineness modulus ranged from 1.81 to 2.07. The mean effective size (size for 10% passing) averaged 0.080 mm, with the uniformity coefficient (ratio of size at 60% passing to size at 10% passing) being about 6.5. The foregoing values

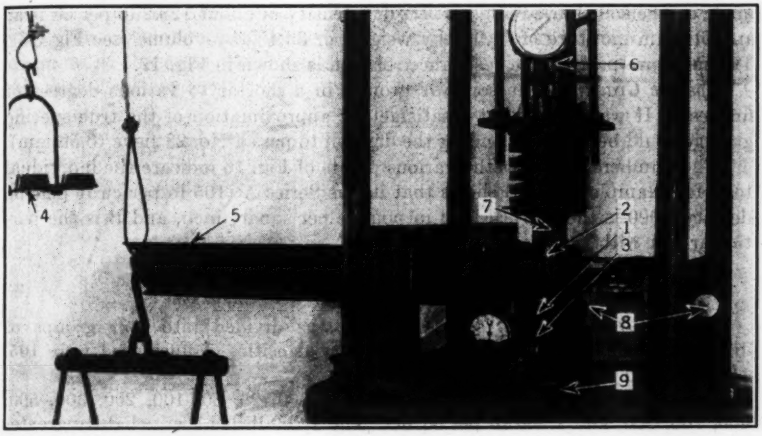

FIG. 15.—SHEAR TEST APPARATUS

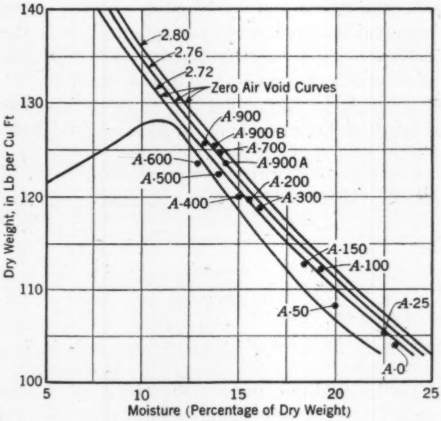

FIG. 16.—DRY WEIGHT; ZONE 3

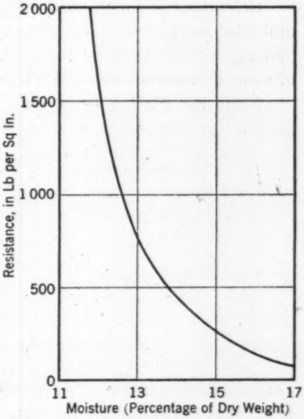

FIG. 17.—PLASTICITY-NEEDLE PENETRATION RESISTANCE; ZONE 3

are for the material screened dry. When the material was screened wet, the average fineness modulus dropped to 1.45 with a corresponding drop in the effective size and increase in the uniformity coefficient.

Compaction and Penetration Resistance.—An average of six compaction tests made on the soil showed a maximum dry density of about 128.2 lb per cu ft at an optimum moisture of 11.0% by weight, or 30.4% by volume (see Fig. 16). The moisture-penetration resistance relation is shown in Fig. 17.

Specific Gravity.—The soil was ground in a mortar to various degrees of fineness. It was found that a satisfactory approximation of the true specific gravity could be had by grinding the dry soil to pass a No. 28 sieve (0.59 mm).

The numbers shown at the various points of Fig. 16 indicate the individual test; for example, A-900B shows that it was Series A (105 lb per cu ft placing density), 900 is the vertical load in pounds per square inch, and B is the particular test with this vertical load.

TEST FEATURES

Placing Density.—The series of tests was divided into four groups of different placing densities. The placing dry densities of fines used were 105, 110, 115, and 120 lb per cu ft.

Vertical Load.—The vertical loadings were 0, 25, 50, 100, 200, 300, 500, 600, 700, 900, and 1,200 lb per sq in. The 1,200-lb load was slightly greater than that recommended by the hydraulic jack manufacturer. Consequently, all tests at 1,200 lb per sq in. vertical load were dropped from consideration.

Rebound.—At the completion of each individual test the dry density of the material within the slip ring at removal was corrected for rebound from the density at the time of incipient failure. This was the density used in determining the degree of saturation at the time of incipient failure.

Incipient Failure.—It was quite simple to determine the point of incipient failure for the quick tests. The relation between time of loading and horizontal displacement was plotted on logarithmic paper (Fig. 18). It is seen that there appear to be two distinct trends, one being plastic displacement with respect to time and horizontal loading and the other being beyond stability. Therefore, the point of intersection can be called the time of incipient failure.

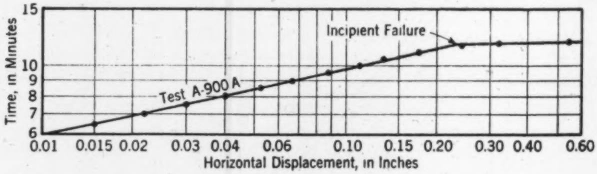

FIG. 18.—LOCATION OF POINTS OF INCIPIENT FAILURE FOR QUICK TESTS

It was not always possible to determine the point of incipient failure in this manner for the slow tests. However, failure of the material generally resulted shortly after the horizontal displacement had passed 0.2 in. At this point a small increment of horizontal load caused failure. The relation between horizontal and vertical pressures at that instant was used in determining the shear coefficient.

Horizontal Load.—The shearing stress was determined by dividing the horizontal load, applied by the lever, by the shear area, after the latter had been corrected for reduction due to the horizontal displacement. No correction was made in the compressive stress due to the vertical load because of the horizontal displacement.

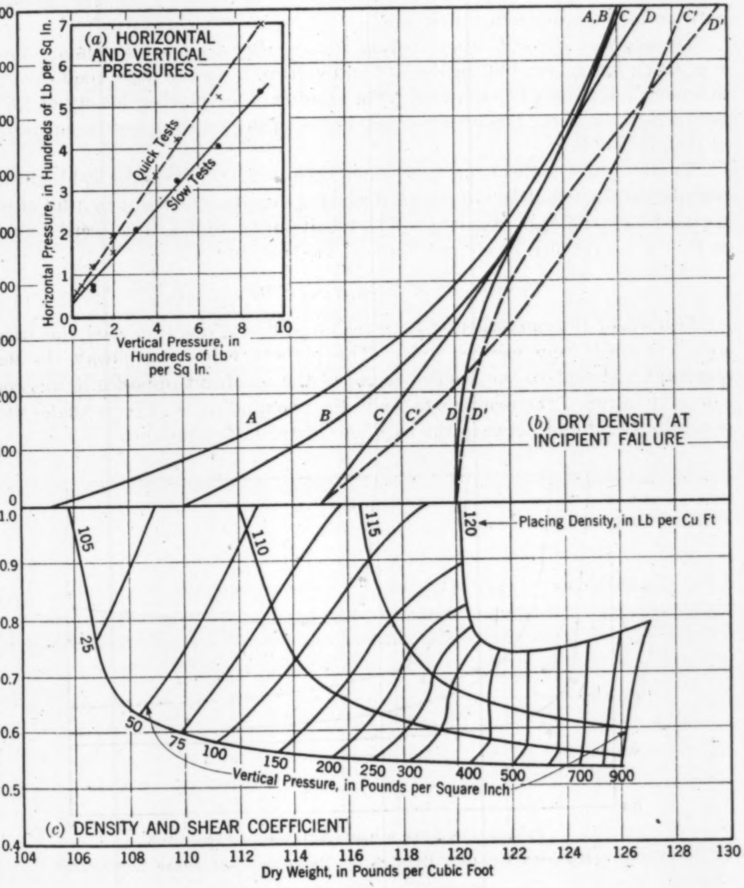

FIG. 19.—TEST RESULTS; ZONE 3

RESULTS

Shear Coefficient.—Fig. 19(*a*) shows the relation between the vertical pressure and the horizontal pressure (in thousands of pounds per square inch) required to reach incipient failure for the series having a placing density of 115 lb per cu ft. This relation is typical of the four series conducted. The shear coefficient is the ratio of horizontal pressure to vertical pressure.

Consolidation.—Fig. 19(*b*) shows the density attained by the soil at incipient failure under the various vertical pressures. There was no appreciable difference between the slow and quick tests for the two lower placing densities ($A = A'$, $B = B'$). However, there was a noticeable increase in density for the quick tests over the slow tests for the two higher placing densities ($C' > C$, $D' > D$). Obviously the influence of the placing density decreases with an increase in vertical pressure.

Density and Shear Coefficient from Placing Density-Load Relation.—From Fig. 19(*c*), for a given placing density and vertical load, the shear coefficient for incipient failure may be obtained. For example, for a placing density of 117 lb per cu ft and a vertical pressure of 300 lb per sq in. the shear coefficient is 0.70 at incipient failure.

These results confirm the conclusion already drawn from the field and the percolation tests that 120 lb per cu ft placing density will result in a fill of low permeability and high stability. The results of the quick tests were omitted as they substantially agree with those of the slow tests.

PENETRATION RESISTANCE RELATIONS

Features of Determinations.—Four readings, that is one from each quadrant, were obtained from each sample. The highest value was always in that quadrant adjacent to the applied force; in the quadrant opposite it was considerably lower. The readings taken in the two quadrants at right angles were generally equal and between the high and low values mentioned.

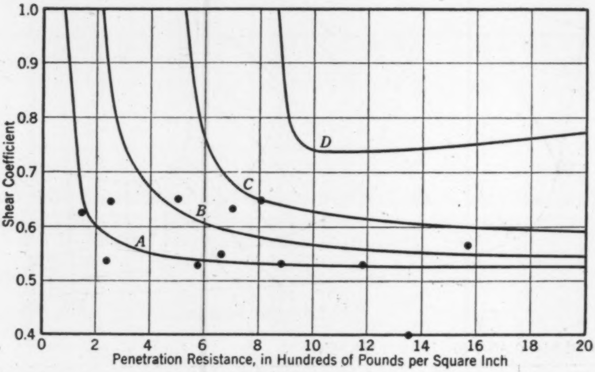

FIG. 20.—RELATION BETWEEN PENETRATION RESISTANCE AND SHEAR COEFFICIENT

Shearing Strength Relation.—A relation between shearing strength and penetration resistance may be derived. The result is shown in Fig. 20. Although it is purely theoretical it shows a characteristic similar to the dry-weight versus shear-coefficient relation curves.

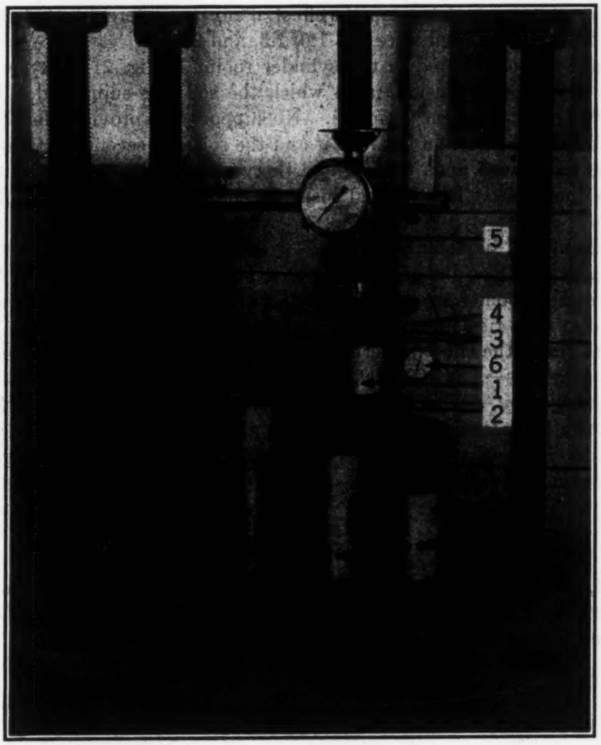

FIG. 21.—LATERAL PRESSURE TEST

The heavy dots represent actual penetration needle readings for 105 lb per cu ft placing density only. They show too wide a spread to check the theoretical relation. Hence, it would appear a hopeless task to predict the shearing strength and with it the stability of similar materials based on the penetration resistance.

LATERAL PRESSURE

The shearing strength may also be determined if the lateral pressure produced by vertical loading is known. With this in mind the following series of tests was conducted:

Method.—The determination of the lateral pressure was accomplished by measuring the change in diameter of a thin cylindrical shell, produced by various vertical loads applied to the soil. By knowing the change in diameter and the modulus of elasticity of the shell material, the value of the lateral pressure can be determined.

Apparatus.—The apparatus (Fig. 21) consisted of four brass cylinders, 1/16 in. thick, 4 in. internal diameter, and of various heights. The object of the different heights was to determine the effect, if any, for different height-diameter of soil ratios. Those used were 0.5, 1.0, 1.5, and 2.0.

The soil was compacted in the cylinder (point 1, Fig. 21). A perforated disk was fitted loosely inside, upon which the soil was supported. This, in turn, rested upon the stem (point 2). No support was provided for the brass cylinder other than friction between it and the soil. A second perforated disk (point 3), was placed upon the soil and the vertical load transmitted through the stem (point 4). The vertical load was produced by an hydraulic jack (point 5).

The change in diameter of the brass cylinder was measured to the nearest 0.0001 in. by an Ames dial gage (point 6). The cylinder wall was divided into several rings of points spaced at regular intervals vertically. Six diameters were used at each ring in obtaining an average change in diameter.

To determine the effect of vertical loads, the test was performed under five different pressures—200, 400, 600, 800, and 1,000 lb per sq in., respectively.

Shear Coefficient.—With the change in diameter and the modulus of elasticity being known the lateral pressure created by the various vertical loads could be calculated. For active thrust with the surface horizontal and for frictionless walls, Coulomb's equation

$$\frac{E}{P} = \tan^2\left(45 - \frac{\phi}{2}\right) \qquad (1)$$

was used, in which E is the lateral pressure, P is the vertical pressure in pounds per square inch, and ϕ is the angle of internal friction. The tangent of ϕ would then be equal to the shear coefficient. For example, since

$$\frac{E}{P} = \tan^2\left(45 - \frac{\phi}{2}\right) \qquad (2)$$

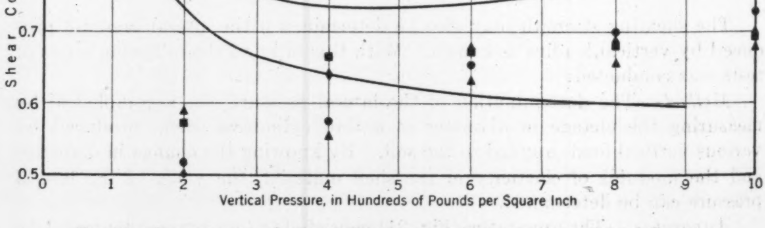

FIG. 22.—COMPARISON OF SHEARING STRENGTHS AS DETERMINED BY DIRECT SHEAR AND LATERAL PRESSURE

it follows that

$$2 \tan^{-1}\left(\frac{E}{P}\right)^{0.5} = 90 - \phi \text{ .... } (3)$$

The angle of pressure transmission is

$$\theta = \tan^{-1}\left(\frac{E}{P}\right)^{0.5} \text{ .... } (4)$$

Then $\phi = 90 - 2\,\theta$; and $\tan\phi$ = coefficient of shear.

The comparison between the coefficient of shear as determined by the lateral pressure tests and by direct shear is shown in Fig. 22.

FIG. 23.—SECTIONS, SAN GABRIEL DAM NO. 1 (SEE FIG. 1)

THE SPILLWAY

As shown in the plan view of the project (Fig. 1), the spillway cuts through the ridge forming the right or west abutment of the dam. The original contract had no provision for this work. The revised or supplemental contract, however, included the provision for the rough excavation of the spillway cut as an auxiliary quarry, known as Unit 2 of Quarry 10. This rough excavation was estimated at 1,200,000 cu yd above El. 1400 and the contractor agreed to quarry this rock and place it in Zone 1 at the regular unit cost of 75¢ per cu yd for rock fill. Without this saving in cost of excavation the project would not have been feasible.

Fig. 23 shows three sections indicated in the general plan view (Fig. 1). At point *A*, Fig. 23(*a*), the concrete floor is 18 in. thick with $\frac{3}{4}$-in. round rods, 12 in. on centers both ways. This floor is laid on a minimum of 8 in. of gravel, with tile underdrains. Contraction joints are approximately 40 ft apart, with copper water seals. At point *B*, the minimum depth of floor is 12 in., being laid on rock. It has no contraction joints, but 1-in. round anchors 5 ft to 10 ft on centers.

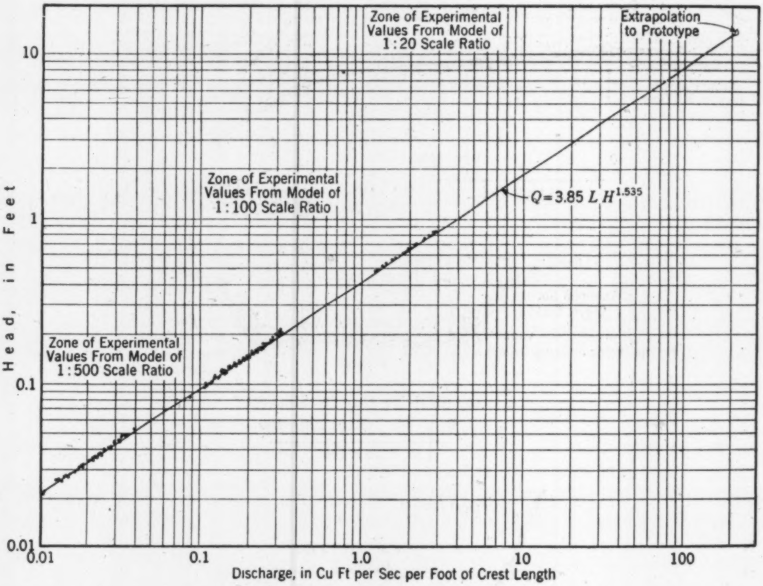

FIG. 24.—RELATION BETWEEN HEAD ON SPILLWAY CREST AND DISCHARGE PER UNIT LENGTH OF CREST

Hydraulic tests were conducted on spillway models. They served to determine:

(1) The discharge coefficient of the overflow section;

(2) The best shape and slope of the spillway channel from a standpoint of both hydraulics and economy; and

(3) The discharge conditions in Brown's Gulch.

Fig. 24 shows the result of the coefficient tests which were conducted on models of three different scales—namely, 1 : 20, 1 : 100, and 1 : 500. It shows that the discharge for all models and probably also for the prototype can be expressed by the equation

$$Q = 3.85\,L\,H^{1.535} \qquad (5)$$

Hence the weir coefficient $\mu = 0.74 =$ constant because $\frac{1}{1.535}\sqrt{2\,g}\,\mu = 3.85$.

This parabola satisfies only those tests that were not affected by backwater. Adhering to the conventional head exponent of 1.50 the same tests are satisfied if the weir coefficient is varied between 0.61 and 0.80. This exponent, however, strictly applies to free discharge only—that is, for atmospheric pressure above the upper and below the lower nappe. This was not the case here and very seldom is with ogee sections in general. Hence, there seems to be no reason why a correction of the pressure head exponent should not be more logical than the variation of the weir coefficient.

Based on these model tests it is believed safe to assume that at least 290,000 cu ft per sec would be discharged through the spillway before the dam were overtopped. This happens to be about three times the peak flow into the reservoir during the flood of March 2, 1938, and more than six times the peak flow on record prior to that date.

The heterogeneous character of the rock, in place, called for a spillway channel with side walls independent of the rock cut. Hence counterfort walls with a 1 on 0.5 face batter and backfilled with gravel against the rock were provided as shown in Fig. 23(*a*) and 23(*b*).

For the same reason the floor slab was placed on a gravel mat in the upper (that is, relatively flat) part of the spillway channel. Stops, in the form of shallow concrete anchors on circular lines, were provided for the stability of the slab as shown in Fig. 23(*a*). A system of drains was provided under the slab and the backfill behind the side walls.

Fig. 23(*c*) shows a section through the waste channel.

THE OUTLET WORKS

The outlet works were incorporated in the diversion tunnel which directed the stream flow through the east or left abutment during construction of the dam. Fig. 25 shows the general arrangement. The cross section of the dam and its position relative to the outlet works are indicated in Fig. 25. The valve chamber at Station 9, Fig. 25, contains four units: Two 123-in. butterfly valves; one 96-in. butterfly valve; and one 51-in. butterfly valve.

At Station 21 there are: One 51-in. butterfly valve; two 51-in. by 39-in. needle valves; one 39-in. by 75-in. energy absorber; one 24-in. by 60-in. energy absorber; one 30-in. by 24-in. needle valve; one 30-in. butterfly valve; one 12-in. by 9-in. needle valve; one 102-in. by 90-in. needle valve; and two 129-in. by 117-in. needle valves. Section *A-A*, in Fig. 26, shows the diversion or outlet tunnel to be circular in cross section and 30 ft in the clear. The capacity of the outlet works was based on the regulation of a so-called 50-yr capital flood, with a peak of 118,000 cu ft per sec to a maximum outflow of 50,000 cu ft per sec.

The necessary outlet capacity was thereby found to be 14,000 cu ft per sec with the water surface at the spillway lip.

A cylindrical trash-rack tower, circular in cross section, was provided at the intake end. Its principal design features are evident from Fig. 27. The four heavy columns, diametrically opposite, serve to make the structure earthquake resistant. This feature will become increasingly important with the anticipated future raising of the tower in keeping with the siltation of the reservoir. In this connection the design provided the blocking off by means of solid plain concrete of one or more lower tiers of trash-rack panels and the adding on top at least an equal number of tiers or stories of new trash-rack panels.

FIG. 25.—LONGITUDINAL SECTION ON

The gross area of trash racks initially provided was 5,920 sq ft or a net area of 4,950 sq ft after deduction is made for the bars. The velocity through the racks for the maximum discharge is 3.0 ft per sec.

Although the solid cylinder shell of the tower, including its base slab, was designed for pressures due to silt and water up to the spillway crest, the metal bars and ring girders supporting them were designed for pressure due to the water surface 50 ft above the top of the tower.

Approximately in line with the axis of the dam (Fig. 25) a concrete plug 100 ft long was provided with a chamber roughly ellipsoidal in shape immediately downstream from it. It was naturally desirable to place the plug as far downstream as possible in order to shorten the lengths of the penstocks. Obviously the feature governing the location was the allowable unbalanced internal pressure in the tunnel above the plug. Due to its seamy character, the rock was expected to carry some seepage water unless special provisions were made to stop it. As previously described, the cutoff wall and grout curtain along the upstream contact of Zone 2 were used to prevent this seepage.

Center Line of 30-Ft Tunnel

Although this provision, combined with the 6-in. shotcrete blanket under Zone 2, was believed to be an effective seal against water percolating around the ends of the dam and under it, no artificial seal was provided to prevent water from percolating through the left abutment due to direct contact with reservoir water as the overburden there was considered highly impervious and the path of percolation relatively long. Hence a conservative assumption had to be made as to the probable effective gradient of water percolating through the left abutment more or less parallel to the tunnel. This led to the maximum allowable excess internal pressure based on the strength of the existing tunnel lining.

The anchorage of the plug was provided by means of saw-tooth recesses in the existing tunnel lining. It was designed to safely resist full reservoir pressure combined with the maximum pull due to thermal contraction of the penstocks. Facilities for the grouting of the contact zone between the plug and tunnel lining, particularly in the upper half, were provided in the design. At the upstream end of the plug a ring curtain of grout was provided by means of radial grout holes extending about 20 ft into the rock.

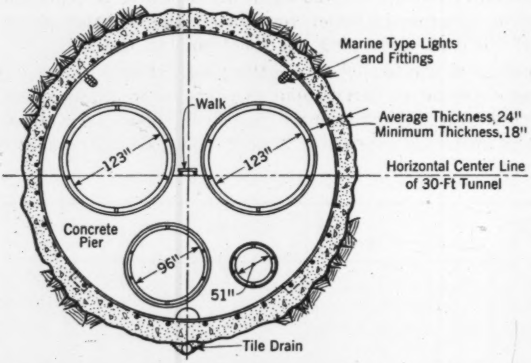

Fig. 26.—Section of 30-Ft Tunnel (*A–A*, Fig. 25) Showing Arrangement of Outlet Pipes and Supports

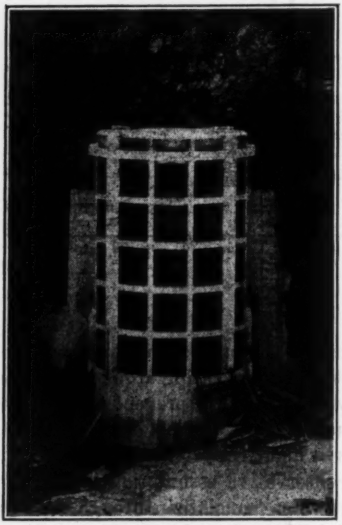

Fig. 27.—Trash-Rack Tower

The chamber immediately below the plug was to house the butterfly valves forming the upstream control of four penstocks (Station 9, Fig. 25). The design allowed these butterfly valves to be operated by means of hydraulic cylinders, the latter being actuated by means of centrifugal oil pumps, capable of producing a static pressure of 3,000 lb per sq in.

At the lower end of the penstocks, needle valves were provided as well as certain diversion facilities for low-water flow. The penstocks were designed on the ring-girder principle with the pier supports 40 ft apart. The design further provided fixed ends with initial tension.

The penstocks were to be fabricated—that is, machine welded in 40-ft lengths in the shop, with provision for field-riveted joints and welded seams. An internal enamel coating approximately $\frac{1}{8}$ in. thick was to be applied by a centrifugal process. The joints were to be treated by hand application of the enamel in the field.

The hydraulic gradients were computed upon the following assumptions:

Entrance losses—

Trash rack (through the bars)	$0.5 \frac{V^2}{2g}$
Outlet tunnel (in the tunnel)	$0.065 \frac{V^2}{2g}$
Plug (in the plug)	$0.10 \frac{V^2}{2g}$

Friction losses (Manning's *n*)—

In the tunnel	0.013
In the plug	0.011
In the pipe	0.011

Valve losses—

Butterfly valves (in the pipe)	$0.32 \frac{V^2}{2g}$
Needle valves (at the outlet and including velocity head)	$1.562 \frac{V^2}{2g}$
Venturi tube losses (in the pipe)	$0.02 \frac{V^2}{2g}$

Approximately 300 ft upstream from the needle valves (Station 18, Fig. 25) venturi tubes were provided in all of the penstocks for the purpose of measuring the flow. Remote controlled flow-indicators and recorders were provided at the needle valves and in the control house, respectively.

CONSTRUCTION OF THE REVISED PROJECT

On August 12, 1935, the revised design was approved by the California state engineer, and on August 13 construction work was resumed.

Rock-fill material underlying Zones 2 and 3 was excavated and moved to Zone 6 as indicated in Fig. 2. Simultaneously the contractor started work on a large "grizzly" plant in Quarry 10, Unit 1 (original quarry) with a peak capacity of screened materials of 1,600 cu yd per hr. The plant arrangement was perhaps one of the boldest ever used. It is shown in Fig. 28. At the toe of the existing, nearly 600 ft high quarry face, a concrete tunnel was built to protect the "grizzly" mechanism and the loading trucks from falling rock. The excavated quarry material was dumped from the edge of the cut into a chute, blasted out of the quarry face, where it partly slid and partly fell down into a receiving crater, formed by a loose rock rim immediately above the "grizzly."

With the "grizzly" in motion the material would "crawl" along the slanting "grizzly" bars, pieces greater than 6 in. by 9 in. moving over the bars and into a waiting 24-yd truck and pieces smaller than 6 in. by 9 in. including fines falling through the openings into hoppers below the floor of the tunnel. The hoppers fed this material on to a belt conveyer which lifted it into two storage bins of about 400 cu yd capacity each, shown in the foreground of Fig. 28. From these bins it was loaded into 24-yd trucks and hauled to the dam.

Immediately after completion of excavation of the old rock fill under Zones 2 and 3, the placing of compacted materials was begun. Specially designed sheepsfoot rollers were used, each two-drum unit (as previously stated) weighing about 25 tons. The minimum bearing pressure of each foot was 375 lb per sq in.

FIG. 28.—VIEW OF QUARRY 10

The cutoff wall across the canyon bottom had already been completed prior to the shut-down. Its extension, first on the east side and afterward on the west side, was now begun. The depth of the cutoff was estimated at 50 ft at the base and 25 ft at the top of the dam. It was excavated to sound rock either as a continuous trench or a series of shafts.

Special excavation was made where faults crossed the cutoff wall. According to specifications the cutoff wall had to be extended along these faults to a depth equal to one half the static head measured at the intersection of the fault with the top of the cutoff wall.

Grout holes varying from 1 in. to 8 in. in size and 100 to 150 ft in depth were drilled along the cutoff in two rows, 5 ft apart. The holes were spaced a maximum 10 ft on centers and staggered. The smaller holes, those 2 in. in size or smaller, were drilled with diamond core drills whereas the 8-in. holes were drilled by blast hole drills. The former were pressure grouted in the usual way and the latter served to apply the circulation method of grouting.

The principal excavation of the abutments was done in the conventional manner by benching from the top down and the rock surface in contact with the rock fill was stripped by means of a dragline which worked from the fill level to a height somewhat in excess of the next lift. The rock fill was placed in 25-ft lifts.

Special attention was given to the stripping of the rock surface under the shotcrete blanket, and a reasonably careful stripping job was done along the contact with Zone 3. Fig. 29 shows stripped areas and grouting operations.

To produce the water necessary for the sluicing of the loose rock fill and the sprinkling of the compacted rock and earth fill two 400-hp turbine pumps were installed in a sump below and one 150-hp turbine pump above the dam.

Monitors were used for the sluicing of the loose rock in Zones 1, 4, 5, and 6 and sprinkling trucks were used to supply the necessary moisture for the compaction of Zones 2 and 3.

The placing density of the fines in Zones 2 and 3 was checked by means of tests throughout the job. A total of 2,250 tests were taken in Zone 2 and 5,221 in Zone 3. This amounts to one test for every 500 and 620 cu yd, respectively, of materials placed. The average placing density was 117.3 and 122.20 lb per cu ft for Zones 2 and 3, respectively. Hence the actual average placing density was more than 2 lb greater than the specified one. The average unit dry weight of Zone 3 material, including rock and fines, was 144 lb per cu ft, when placed. It was probably raised to an average of 150 lb or more due to self-compaction. It assumed the properties of good concrete or artificial stone. The average moisture content was 5% of the dry weight of rock and fines combined. The 1¾-yd-dragline bucket was unable to "bite" into this mass until it had first been loosened with suitable tools.

FIG. 29.—GROUTING AND DRILLING OPERATIONS

An unusual opportunity offered itself to measure the actual consolidation when the fill reached a height of some 70 ft above bedrock. At this level an abandoned power tunnel 4 ft by 6 ft in size, "day-lighted" near the axis of the dam, and had to be sealed by means of a 20-ft concrete plug. As the tunnel afforded access to the back of the plug it was possible to observe the settlement of the Zone 3 fill by means of manometers. These manometers consisted of two calibrated vertical glass tubes ½ in. (inside diameter) connected to ½-in. copper tubes. These copper tubes were installed inside of 2-in. standard pipe and extended some 75 ft and 150 ft, respectively, into the fill. The copper tubes and 2-in. pipes were bent up at the fill end, the former being open and the latter capped. They were placed on an initial slope of 1%, the fill end being higher than the tunnel end.

By filling the copper tubes with water from the tunnel end it was possible to establish the elevation of the open end of the copper tubes by means of the manometer tubes.

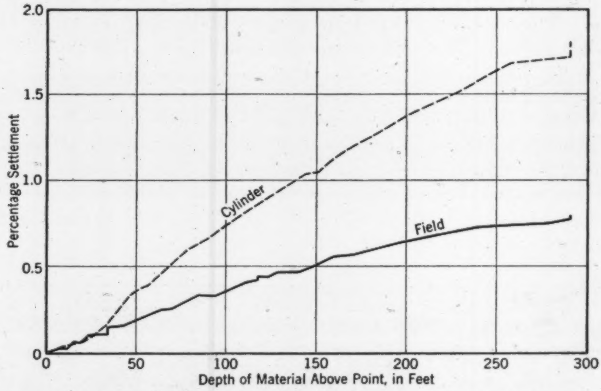

Fig. 30.—Settlement, Zone 3, Showing Relation Between Field and Laboratory Tests

Simultaneously Zone 3 material was placed in one of the 24-in. cylinders in the laboratory at the same average density as had been established for Zone 3 up to that level. The cylinder was freed from the base to minimize arching, as previously outlined. Vertical pressures corresponding to those due to Zone 3 fill above the tubes were brought to bear on the material in the cylinder, and the settlements were recorded. The results are shown in Fig. 30.

Overfill and Settlement (Revised Project)

Overfill to allow for residual settlement was provided as follows: None at the toe of the upstream slope, with a linear increase to maximum 2 ft at the crest; and none at the toe of the downstream slope, with a linear increase to maximum 3 ft vertically above the toe of Zone 3 and a linear decrease to maximum 2 ft at the crest.

Maximum vertical settlements to July, 1941, were as follows: 0.40 ft at the crest and 1.57 ft vertically above the toe of Zone 3. Under nearly full water load, the dam showed a maximum downstream deflection of 0.11 ft at the crest. With the emptying of the reservoir the crest returned substantially to its initial position.

The rock was quarried in 50-ft lifts by means of blast holes. Approximately 0.6 lb of black powder was used per cubic yard of solid rock. Including waste due to the original design as well as abutment excavation, a total of about 10,000,000 cu yd of solid rock was blasted.

The average production for two eight-hour shifts (6 days per week) was 26,000 cu yd of rock per day, placed in the dam. The maximum daily production was 42,000 cu yd and maximum monthly 975,000 cy yd. An average of 750 men were employed. Fig. 31 shows the construction of the dam completed and the spillway construction in progress.

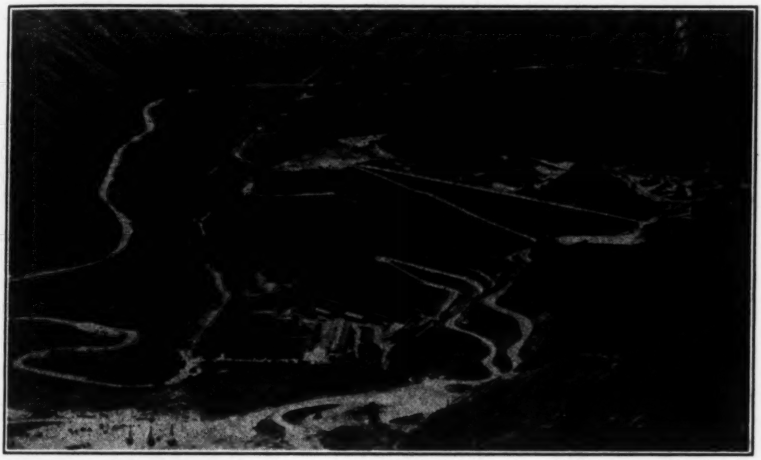

FIG. 31.—SAN GABRIEL DAM NO. 1, COMPLETED; SPILLWAY UNDER CONSTRUCTION

PERCOLATION THROUGH THE DAM (REVISED PROJECT)

Based on the actual placing densities of material in Zones 2 and 3 and the corresponding permeability conditions, a study was made on the percolation through the dam with the water surface at the spillway lip for an indefinite period.

The results are shown in the following analysis, which is based on Darcy's law of laminary flow through soil:

$$\Delta Q = K\, i\, \Delta A = K \frac{\Delta h}{\Delta L} \Delta D \qquad (6)$$

in which: ΔQ = flow in cubic feet per year per longitudinal foot of dam between two adjacent flow lines; i = hydraulic gradient for any path of flow; K = coefficient of permeability expressed as velocity in feet per year for unit area of flow and a hydraulic gradient of one; Δh = head or pressure interval in feet; ΔL = path interval in feet; and ΔA = area interval per unit length of dam in square feet = $\Delta L \times 1$. The flow net consists of flow lines and equipotential lines. The latter are perhaps better defined as equipiezometric lines. They are normal to each other and for equal head intervals form a system of squares or quasi squares as shown in Fig. 32. The flow lines are spaced such as to have equal flow ΔQ through any area interval ΔA between two flow lines. Hence, because $\Delta D = \Delta L$, Eq. 6 becomes

$$\Delta Q = K\,\Delta h \qquad (7)$$

The coefficients of permeability K_1 and K_2 for Zones 2 and 3 were found from samples of test holes to be 0.35 and 1.05 ft per yr, respectively.

Continuity of flow through Zones 2 and 3 requires that

$$\Delta Q = K_1\,\Delta h_1 = K_2\,\Delta h_2 \qquad (8)$$

or

$$\frac{K_1}{K_2} = \frac{\Delta h_2}{\Delta h_1} = \frac{0.35}{1.05} = \frac{1}{3} \qquad (9)$$

The flow net was constructed by trial and error. The flow through the dam was determined as follows:

$$Q = n_1\,\Delta Q = n_1\,K\,\Delta h = \frac{n_1\,K\,h}{n_2} \qquad (10)$$

in which: n_1 = number of flow paths and n_2 = number of head intervals. Hence, for Zone 2,

$$Q = \frac{K_1\,h\,15}{16} \qquad (11a)$$

and, for Zone 3,

$$Q = \frac{K_2\,h\,5}{16} \qquad (11b)$$

Let $h = 303$ ft; $K_1 = 0.35$; and $K_2 = 1.05$. By Eqs. 11, therefore, $Q = 99.50$ cu ft per yr, and

$$V_{\max} = K_2\,\frac{\Delta h}{\Delta L_{\min}} \times \frac{1}{(\%\ \text{voids})} \qquad (12)$$

That is, $V_{\max} = 1.05 \times \frac{303}{16 \times 20 \times 0.16} = 6.20$ ft per yr.

THE SPILLWAY

The spillway was constructed under separate contract. It was begun in June, 1937, and was completed in May, 1938. The spillway channel proper (that is, the concrete ogee section, walls and floor) was completed two weeks before the flood of March 2, 1938, at which time the spillway carried 57,000 cu ft per sec. Fig. 33 shows typical features of the spillway construction.

THE OUTLET WORKS

The installation of valves and penstocks was done under separate contract. The 51-in. butterfly valve and penstock were installed first and served to control the low-water flow of the river. For this purpose the piers were built in sections. The 96-in. butterfly valve and penstock were installed next. This latter work was in progress at the time of the flood. Hence the outlet works

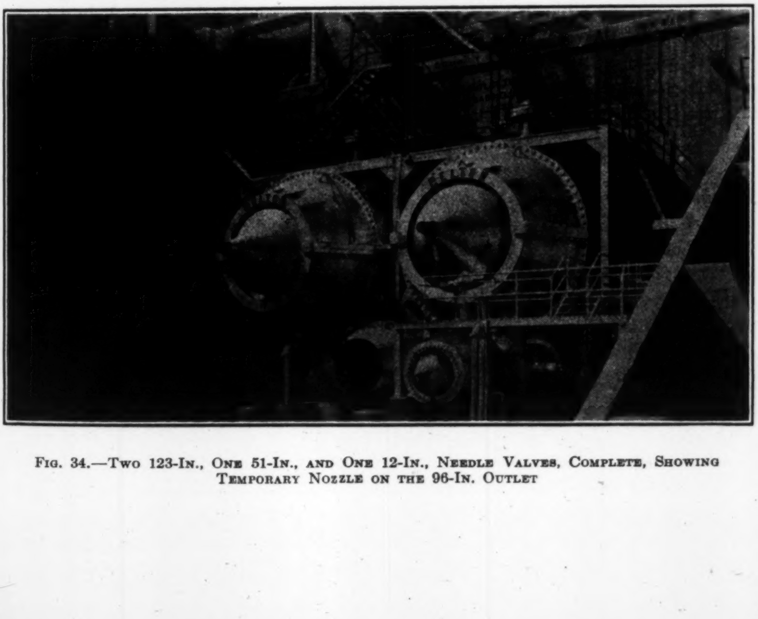

Fig. 34.—Two 123-In., One 51-In., and One 12-In., Needle Valves, Complete, Showing Temporary Nozzle on the 96-In. Outlet

tically in the course of one day, approximately 75% of which consisted of sand and silt. This quantity happens to be about equal to the total yardage of rock and earth fill "expeditiously" placed in the dam over a period of two years!

The installation of the outlet works was completed in October, 1938. Fig. 34 shows the installation of the outlet works completed.

During April, 1940, tests were conducted on the penstocks to ascertain the actual energy losses versus the theoretical ones. The initial water surface in the reservoir was at El. 1360±. Hence the head was ±60% of the design head (water surface at the spillway lip). The results are shown in Table 6.

It is of interest to note that these tests were made at very high values of Reynolds' number, which extended from 2×10^6 to about 3.8×10^7 for the highest flows in the large pipes.

The maximum height of the dam above its foundation is 376 ft. Therefore, it may claim the distinction of being the highest dam of its type in the world at this time.

QUANTITIES AND COSTS

A summary of the estimated and final quantities and their handling costs, is presented in Table 7.

ACKNOWLEDGMENTS

Credit is due S. M. Fisher, M. Am. Soc. C. E., chief engineer of the District from September, 1934, to February, 1935, under whose supervision the revised design of the dam was prepared in its essentials.

C. H. Howell, M. Am. Soc. C. E., was chief engineer of the District from February, 1935, to October, 1938. By his untiring efforts, he succeeded in the elimination of seemingly unsurmountable obstacles to make the completion of the project possible in accordance with the revised design, which had been supplemented and perfected under his supervision.

The writer is indebted to H. E. Hedger, M. Am. Soc. C. E., chief engineer of the Los Angeles County Flood Control District, for valuable advice and for making District records available for the preparation of this paper.

DISCUSSION

E. Soucek,[3] **Jun. Am. Soc. C. E.**—This discussion is confined to Fig. 24 and one of the author's comments in connection with it. The ranges of heads plotted for each model and the corresponding prototype ranges (in feet) are approximately as follows:

Model	Model heads	Prototype heads
1 : 20	0.50 to 0.85	10 to 17
1 : 100	0.10 to 0.20	10 to 20
1 : 500	0.02 to 0.05	10 to 25

It may be that there was no necessity for discharges corresponding to heads lower than about 10 ft. If this was the case, the tests served their purpose but they do not justify the author's statement (see heading "Spillway") "that the discharge for all models and probably also for the prototype" can be expressed by Eq. 5. This inference should be qualified as to the range of head within which the formula is to be applied. The conformity between the models is excellent in the range of heads compared. An extension of the comparison to lower heads would be equally valuable and interesting.

William P. Creager,[4] **M. Am. Soc. C. E.**—For his able description of the tests, design, and construction of this notable dam, the author is to be congratulated. The consulting engineers on this work (L. F. Harza, M. Am. Soc. C. E., and the writer) and the chief engineer (Mr. Howell) advocated a somewhat smaller section for this dam, the finally adopted section being a compromise between their ideas and those of the state engineer's consultants. This point is indicated in view of the steeper slopes adopted for subsequent designs of dams of similar type.

The writer cannot agree with Mr. Baumann's method of stepping up to the prototype the results of tests of the three models as shown in Fig. 24; nor can he agree with the statement (see "The Spillway") that the discharge for all models and probably also for the prototype can be expressed by Eq. 5, having an exponent of 1.535.

In the three models and the prototype, consider, respectively, homologous heads of 0.03, 0.15, 0.75, and 15.00 ft for the scale ratios of 1 : 500, 1 : 100, 1 : 20, and 1 : 1 (prototype). The test head of 0.03 ft in the 1 : 500 model, of course, is entirely too small for consideration on account of the relatively great influence of skin friction. The test head of 0.75 ft in the 1 : 20 model should closely simulate the action of the prototype since, for that size, the influence of skin friction, with a properly constructed model, is negligible.

Beginning with a head of 0.75 ft in the 1 : 20 model and a flow Q of 2.475 cu ft per sec, and assuming that the true exponent is 1.5:

$$Q = 3.81\, H^{1.5} \qquad \text{.......................(13)}$$

If this parabola were plotted in Fig. 24 it would give $Q = 221.0$ for the homologous head of 15.0 ft in the 1 : 1 prototype instead of 246.0 determined by the author.

---

[3] Iowa City, Iowa.

[4] Cons. Engr., Buffalo, N. Y.

Similarly, the corresponding homologous discharge for the homologous head of 0.03 ft, in the 1 : 500 model, is $Q = 0.0198$ instead of the measured discharge of $Q = 0.0177$. The lower measured discharge is accounted for by the relatively greater effect of skin friction.

JOSEPH JACOBS,[5] M. AM. SOC. C. E.—This is a splendid paper, presenting in commendable detail the procedures and technique of design and construction, and many of the results obtained in the actual building of a very important and somewhat unusual earth and rock-fill dam structure. It is desired to refer briefly to a few of the items discussed in the paper.

(1) *The Original Design.*—It is not clear why entirely adequate tests of quarry composition, as to the proportions of fine and coarse materials that would probably be yielded, were not made in advance of the preparation of plans and specifications. Presumably, more extensive tests than apparently were made would have avoided, or at least materially lessened, the train of unfortunate events (not fully discussed in the paper) that resulted from the lack of correct foreknowledge as to quarry composition. A dam structure of magnitude always justifies thorough and extensive advance exploration for required construction materials, foundation conditions, etc.

(2) It seems also, to the writer, that the specifications imposed too severe an exclusion of the fines, particularly in view of the fact that the rock was to be placed dry. The inclusion in the rock-fill section of a dam of a fair proportion of such fines, for example, as were eliminated by the original specifications, makes for a denser and more stable structure (even though the friction coefficient may be somewhat decreased) and one that is satisfactory as to permeability. In the present case, as was disclosed soon after construction was begun, the disparity in the proportions of coarse and fine material of Quarry 10 was too great to warrant construction, economically, of a rock-fill dam with borrow from that source.

(3) *The Revised Design.*—The assumption, or rather the crediting, of no sliding resistance to Zones 1 and 2 in determining dam stability was in the direction of increasing the factor of safety against sliding failure, but that assumption may be regarded as too severe, for those zones definitely do have appreciable sliding resistance, particularly Zone 1 with its dominant rock content and with a shear coefficient probably not less than 0.75. An alternate, and perhaps a more economical procedure, would be to assign their nearest probable value to all zone resistances, rather than to ignore some of them as was done for Zones 1 and 2, and then apply a conservative over-all safety factor to the entire cross section of the dam, or to such portion of it as was involved in the plane or curved surface of least shear resistance. It is hoped that the author, in his closure, will indicate the location of the critical line of shear weakness and just how he obtained his necessary average shear coefficient of 0.37. For a horizontal section at the base of the dam, the shear coefficient would seem to be less than 0.37 for a safety factor of one, although that value must, of course, be appreciably exceeded for assured safety.

---

[5] Cons. Engr., Seattle, Wash. (Mr. Jacobs died on March 16, 1942.)

(4) It is difficult to obtain entirely dependable cohesion and friction factors by laboratory tests and both caution and good judgment are required in making, interpreting, and applying such tests to full-size embankment conditions. This is particularly so because laboratory tests are made on practically homogeneous soil samples, whereas embankments are rarely, if ever, entirely homogeneous. Laboratory tests, however, are indispensable aids in connection with earth-dam design and stability analyses, but their inherent limitations must be recognized and conservative safety factors must always be used in applying the results of such tests to actual design and construction.

(5) The author's several graphs of laboratory tests showing the relationship, under varying conditions, of shear coefficients, vertical pressures, penetration resistances, densities, etc., are all of great interest. Among other things they indicate the following:

> (*a*) That density increases with vertical pressure but at a very much slower rate, and that under high vertical pressure the final densities are practically equal despite appreciable differences in the initial densities at which the samples were tested (Fig. 19(*b*));
>
> (*b*) That, except for sample *D* for the higher pressures, there is a progressive decrease of the shear coefficient with increase of vertical pressure, the initial density remaining constant; and a progressive increase of the shear coefficient with increase of initial density, the vertical load remaining constant (Figs. 19(*c*) and 22); and
>
> (*c*) That, except for sample *D* for the higher pressures, there is a progressive decrease of the shear coefficient with increase of penetration resistance, the initial density remaining constant; and a progressive increase of the shear coefficient with increase of initial density, the penetration resistance remaining constant (Fig. 20).

(6) Each of the indications cited, when considered alone, seems to be logical and, apparently, is in general accord with observations elsewhere; but a comparison of the shear coefficients for varying vertical pressures (Fig. 19(*c*)) with those for varying penetration resistances (Fig. 20), for identical arguments in pounds per square inch, shows differences that are not so readily accounted for. These differences vary irregularly and range from zero to 70% or more, the higher shear values being those pertaining to penetration resistances. To be sure, vertical pressure and penetration resistance, as now determined, are not identical, and, although the latter is intended primarily as a quick field index of density and moisture content, yet it would seem, if it were accurate, that it also should be, in so far as shear values are concerned, a fair index of pressure equivalence even though its technique does differ from that of the normal pressure test.

(7) The preceding statement is not intended to imply that the laboratory tests were in any sense below par (apparently, they were all carefully made) but merely to indicate that such tests are not free of difficulties and limitations that may mar results, and also to emphasize that there is yet much that is elusive, vague, and unknown in the field of soils mechanics, particularly in the relationship of shear, internal friction, and cohesion. It is suspected that

part of the cited difference in shear values is due to the fact that the present usual method of determining penetration resistance is not very accurate. Too much of the personal equation enters into that determination, involving, as it does, both the time rate and the intensity of man-power load application. Some new device should be developed that will largely eliminate the personal equation and permit more accurate correlation to density and supporting power of the soil. Such a device might take the form of a small fixed weight falling through a fixed height on a penetration needle of known diameter, and with a gage or scale calibration correlated to fairly large-size pressure tests on the same soil as that of the penetration needle tests. A series of such tests should afford a fairly dependable correlated calibration for manufacture of the apparatus.

(8) It is also possible that the generally accepted formula for shear may not be, and probably is not, entirely correct. It usually takes the form

$$F_t = C + f P \quad \text{(14)}$$

in which F_t = total shear resistance; C = total cohesion resistance, or total resistance at zero loading, the cohesion per square foot being regarded as a constant for a given soil; f = coefficient of internal friction, regarded, usually, as a constant for a given soil; and P = total imposed vertical load.

It is the writer's concept that both total friction and total cohesion increase with density and with vertical loading; that the coefficients of friction and cohesion generally decrease with increase of vertical loading; and, as previously stated, that soil densities increase with vertical loading at a greatly retarded and progressively decelerating rate. On the basis of these concepts the shear formula might take the basic form,

$$F_t = C + c P + f P \quad \text{(15)}$$

in which the additional factor, c, is the coefficient of cohesion. The thought is that C is a base constant for a given soil and for a specific standard dry density, say 100 lb per cu ft, and that c and f are not constants but are variable functions of P—probably exponential functions and not identical for c and f. Only extensive laboratory tests correlated to proper mathematical analysis can determine what these functions are and what the equation in its final form should be.

(9) *Roller Tests, Zone 3.*—Fig. 9 seems to indicate that the lower compaction costs resulted from the use of the heavier roller units with relatively few passes rather than from the lighter units with a larger number of passes. Apparently, the lowest unit cost, particularly if considered on the basis of cost per cubic yard, or cost per square foot per ton-pass of roller, was for eight passes of the tandem combination, consisting of one double unit, loaded with sand and water, and one double unit, unloaded. The indicated initial unit cost, however, is not necessarily the final single criterion as to the best roller combination to be adopted. The final dry densities desired, and those actually attained under the different tests, must also be considered, and no doubt were.

(10) It would be informative, and would add appreciably to the completeness of the record as presented in the paper, if the following data were added to

the tabulation immediately preceding Fig. 9, and for each of the roller combinations listed: The average cost of compaction per cubic yard, the average dry density attained at optimum moisture and what that optimum was, and the average travel speed in miles per hour. It would also be of interest if the author, in his closure, would state just what roller combination, and just what number of passes were actually used, in the construction of Zone 3.

(11) *Densities.*—The densities attained in San Gabriel Dam are a good illustration of what can be accomplished with any reasonably good earth material under the present efficient methods of constant check of the properties of the materials as placed, and unremittent compaction and moisture control during the entire period of embankment construction. The degree of density obtained is largely a question of economics—what one feels warranted in expending for synthetic proportioning and mixing of the constituent materials, and, in compaction effort, to secure the density desired. The Zone 3 dry density of 144 lb per cu ft for material in place, including rock and fines, is perhaps 10% to 15% in excess of that which, in earlier years, was attained or attainable with the equipment then available, and then regarded as acceptably good. There are many intact old embankments whose dry densities are less than 120 lb per cu ft. With its moisture content of 5%, the wet density of the Zone 3 material in place was about 151 lb per cu ft, a density, as the author indicates, comparable to that of good concrete.

(12) Other recent examples of high densities attained in earth embankments are Green Mountain Dam on the Blue River in Colorado, and Deer Creek Dam on the Provo River in Utah, completed in 1941, both being structures of the U. S. Bureau of Reclamation. The former, for its impervious zone, attained an average dry density of about 141 lb per cu ft for the material in place and an average wet density at optimum moisture (±9%) of about 153 lb per cu ft, with departures from about 5% below to 2% above these values. For Deer Creek Dam, the average wet field density of the impervious section was also about 153 lb per cu ft with an optimum moisture somewhat greater than that for Green Mountain Dam. These densities, in the main, were secured with twelve passes of duplex and triplex sheepsfoot roller units, ranging in weight from 1 ton per lin ft of roller, unloaded, to nearly 2 tons per lin ft fully sand and water loaded.

(13) *Seepage.*—The author states that the laboratory tests of Zone 3 material indicate a permeability coefficient of 1.05 (1.05 cu ft per sq ft per yr for unity gradient), a maximum velocity of 6.2 ft per yr (also for unity gradient), and a seepage loss of 99.5 cu ft per yr per lin ft of dam at its maximum section. This means, with reservoir water surface at spillway crest elevation, a total seepage for the structure of less than 0.01 cu ft per sec—an entirely negligible amount. If the data are available, a comparison of the seepage loss as indicated by laboratory test with that of the actual structure in operation at full reservoir stage would be of interest. The writer suspects that the latter is very much the greater.

(14) The fact is that for any acceptably good dam material, properly placed and compacted by modern methods, as already referred to in a previous para-

graph, seepage, as indicated by laboratory test, is almost always negligibly small, and is almost always greatly exceeded by the actual seepage of the finished structure. This by no means implies that the laboratory work is poorly done, or that the dam is not well and carefully constructed, or that the actual seepages exceed safe permissibility although, in some cases, they may be of that character. Usually, the reverse of these conditions prevails.

(15) Seepage through the actual structure is not uniformly distributed; nor is it of uniform intensity, as through an entirely homogeneous mass of uniform density and porosity, such as is practically the case for laboratory tests. Usually, it manifests itself in distinctive areas or sections of the dam where, possibly, a minor shear plane may have developed from slight differential settlement, or where conditions as to compaction or composition of the material itself may have been somewhat below normal. Also, if adequate cutoffs have not been provided, the major seepage may be under or around the ends of the dam. Whatever the cause or causes, however, it may be anticipated that actual seepage will exceed laboratory seepage. It should be appreciated then, that, although laboratory tests are highly informative, indeed indispensable, and are valuable indexes of the comparative impermeabilities of the different borrow-pit materials from which selections must be made for dam construction, they should not be regarded as safe measures of the absolute seepage that will obtain in the finished structure.

Jacob Feld,[6] M. Am. Soc. C. E.—A wealth of data on granular materials and rock fills is contained in this paper. Results of field experience and laboratory tests are correlated with each other and also with actual results in the construction work. The paper merits intensive study not only by the practical engineer who directs the performance of work but even more by the laboratory technicians, because the author clearly describes the type of information needed in the design and construction of rock-fill dams.

In works of such magnitude, the honest and commendable example set by this project, of revising the design after the field organization has had sufficient experience with the materials involved to permit true evaluation of the assumptions upon which the design was based, should be seriously followed. The mathematical development of the design can be beyond any criticism, and the design can be approved "by consulting engineers and geologists of national repute"; yet all of it is based on assumptions of what the materials will be and how they will act. It has been the writer's feeling that no amount of laboratory tests on soils, whether natural or (as in this project) artificial, can give a complete quantitative answer. The best that can be expected is a determination of the limits within which the properties of the soil may range. Such limits may be far apart, and designs of the structure for each limit may be even further apart. Averaging the laboratory results and using such data for an "average" design is not honest, economical, or even safe. When the possible range is large enough, why cannot alternate designs be prepared, or, for a project of this magnitude, several designs, to be adjusted as the true character and action of materials encountered are learned?

---

[6] Cons. Engr., New York, N. Y.

Economical moving of rock by blasting as in excavation work is not always economical rock production in quarry work. As a matter of fact, most economical excavation work is often dependent upon the size of the rock produced, where mucking equipment is limited by space requirements. In the excavation of a rock tunnel portion of the Sixth Avenue Subway in New York, N. Y.,[7] a slower acting dynamite was used to prevent a seamy schist rock from breaking out in slabs too large for the mucking machine. In describing the quarry operation, Mr. Baumann states that only one fourth of the rock was of proper size. There is a description of the type of quarrying and the kind of explosive used, and the writer would like to ask whether tests were made with other explosives and different drilling methods. Certainly, the quarrying of 10,000,000 cu yd of rock deserved a little study.

The tests of consolidation and percolation for different mixtures of fine and coarse materials are of great value. From the data as summarized in Fig. 4 and Table 2, two conclusions can be reached:

(1) The mixture of maximum density does not provide maximum resistance to seepage, because for similar materials the shape of the channels formed by the voids, and not the total percentage of voids, is the chief factor of percolation; and

(2) The mixture of maximum initial density shows the minimum change in density under load, chiefly because the more intimate contact of grains in the mixture of maximum density reduces local overstresses and thereby reduces edge and point crushing within the mass.

The author's attempt to evaluate the shear coefficient by measuring the total earth pressure within a small cylinder is subject to several objections. The validity of the formula for enclosed shallow bins is one objection; another is the variations in total pressure with volume expansion of the retaining cylinder. The direct shear test seems a preferable method for evaluating the shearing coefficient.

The complete coverage of the subject of compaction under various moisture contents, as well as with different equipment, is a valuable contribution. It is noteworthy that saturation practically eliminates breakdown of the grains, whereas the maximum effect of compaction equipment can be obtained when the moisture is between 10% and 15% of the dry weight. The explanation is probably in the tensile strength provided by the moisture films in the granular mass.

That even field tests will not provide accurate estimates of consolidation settlement is shown by Fig. 30, which reports an observation of the actual consolidation of about half the value expected from cylinder tests. One explanation of the discrepancy is in the difference of time during which the same unit loads were applied, as well as the lateral restraint found in the actual dam fill as contrasted with the artificial cylinder restraint with less frictional resistance along the boundary of the test sample inside the cylinder. The action of the completed dam in deflecting under full water load with perfect rebound shows that the structure is substantially elastic in nature; no better test of the excellence of design and performance could be expected.

---

[7] "Tunnel Construction, Sixth Avenue Subway, New York, N. Y.," by Jacob Feld, *Proceedings*, Am. Soc. C. E., April, 1941, p. 617.

WALTER L. HUBER,[8] **M. AM. SOC. C. E.**—As stated by the author, a revised design for San Gabriel Dam No. 1 was approved by the state engineer of California on August 12, 1935. This approval was secured only after many conferences among the state's Board of Consulting Engineers for this dam (F. C. Herrmann, M. Am. Soc. C. E., the writer, and the late Charles D. Marx, Past-President and Hon. M. Am. Soc. C. E.), the chief engineer of the Los Angeles Flood Control District, and the consulting engineers of the District. The section of the dam, although considered conservative, was the minimum which, under all of the local conditions, was satisfactory to the state's consultants.

The capacity of spillway required by the state's consultants was 80,000 cu ft per sec with 15-ft freeboard. Had certain information since secured (partly the record of subsequent floods) been available, it is probable that a larger discharge capacity would have been required. However, the requirement of freeboard that was fixed as a condition is quite conservative, and by encroaching upon this freeboard a discharge that is ample is indicated—this without jeopardy. The model tests referred to by the author lead him to conclude "that at least 290,000 cu ft per sec would be discharged through the spillway before the dam were overtopped." As he states, this is "about three times the peak flow into the reservoir during the flood of March 2, 1938, and more than six times the peak flow on record prior to that date" (see heading "The Spillway").

FEDERICO BARONA,[9] **ESQ.**—The information given in the paper by Mr. Baumann is interesting and constitutes a valuable contribution to the subject of the intelligent use of the materials available, in the construction of rock-fill and earth-fill dams.

The use of gravel or rock as coarse aggregate, bound by a sand-clay mortar, is undoubtedly an efficient manner of increasing the fill density and internal friction. If the coarse aggregate is added properly so that a certain limit is not exceeded, and so that sufficient compaction is assured, the composite fill can be made as watertight as the mixture of sand and clay mortar by itself. "El Palmito" Durango, in Mexico, is an earth-fill dam 280 ft high. In its construction, about 40% gravel was used as an addition to the sandy-clay loams available.

The addition of gravel has been economical since the depth of the layers of sand-clay in the borrow pits is limited by layers of gravel. By using the gravel, the borrow pits close to the site can be excavated to greater depths. Furthermore, the density of the fill has been increased.

The experience obtained in "El Palmito" Dam shows that the gravel-sand-clay mixture can be compacted more satisfactorily by means of smooth rollers. The gravel pieces act like the sheepsfoot elements of a roller to transfer the pressure from the smooth roller to the lower layers. For this kind of material, smooth rollers are more efficient than sheepsfoot rollers, because the latter tend to dislodge the pieces of gravel already embedded in the sand-clay mortar.

[8] (Huber & Knapik), Cons. Engrs., San Francisco, Calif.

[9] Testing Engr., Mexican Commission of Irrigation, Mexico, D.F., Mexico.

The trend in the construction of compacted fill dams must be toward the formation of soil concretes, with improvements in technique, grading, water content, etc., until they are as well known as cement concretes. Of course, if coarse aggregate is used in compacted fills, the friction to overcome is greater and so the compacting equipment must be much heavier.

Soil concretes have not been studied much, because generally, in the soil laboratory, only small specimens are tested, and only the fine portion (sand-clay mortar) can be included. San Gabriel Dam has the distinction of being the first project providing for the testing of larger specimens, with rocks included.

It is of interest to notice that in the beginning of Portland cement investigations, tests were made only on small specimens of neat cement or mortar. Later the technique of testing the entire mass of concrete was developed until 36-in. by 72-in. cylinders were tested.

In the case of soil concretes it would be worth while to determine permeability, settlement, compaction, and triaxial compression strength in specimens (24 in. diameter or more) sufficiently large to include gravel or rock such as is used in the fill.

Tests, in place, for permeability, settlement, compaction, etc., must be given serious consideration. They are especially important in the case of soil concretes as a means of approaching a greater knowledge of the true conditions that occur within the finished fill.

Experimental sections of fill compaction, as observed in San Gabriel Dam, are of great practical importance. In the Mexican Commission of Irrigation it is general practice to make these experimental sections whenever the construction of a new dam is begun. Thus it has been possible to determine many factors of technical and economic importance, such as: Thickness of layers to compact, number of trips for rollers, type and weight of equipment, etc. The measurement of settlement in embankments is also a general practice in the Mexican Commission of Irrigation.

Permeability tests, in place, have been made by the Commission to some extent, but for such an important soil characteristic the cooperation of all those engaged in the construction of earth dams is desirable to establish standard testing methods.

G. H. HICKOX,[10] M. AM. SOC. C. E.—The part of Mr. Baumann's paper that describes the tests on the spillway model, particularly the tests on models at three different scales, is especially interesting. The results of these tests lead to Eq. 5. This equation can be developed if it is assumed that the velocity of flow through a horizontal element of area over the crest is

$$V = \sqrt{2\,g\,H^n} \qquad \qquad (16)$$

in which n is equal to 1.07.

If Eq. 5 with a constant coefficient is valid for the prototype as well as for the model, it leads to the curious relationship that the ratio of prototype discharge to model discharge varies as the 2.535 power of the length ratio instead of the 2.5 power predicted from considerations of dynamic similarity.

---

[10] Senior Hydr. Engr., TVA, Hydraulic Laboratory, Norris, Tenn.

It has been supposed generally that discharge over a prototype spillway would be greater than that predicted from a model because of the relative reduction of friction loss in the prototype, and that the change in discharge would be represented by a change in the coefficient. The points of Fig. 24 seem to be equally well represented by three lines having a slope of 1.5 and different coefficients. It is unfortunate that data on the various models do not overlap.

It would be interesting to know if advantage was taken of the discharge illustrated in Fig. 33(*c*) to obtain a prototype verification of the curve of Fig. 16. Such verification of model tests is rare and is needed acutely.

Paul Baumann,[11] M. Am. Soc. C. E.—In the process of condensing the original text, it was necessary to make certain deletions. Among them was a statement pertaining to the spillway. It appears that this caused certain difficulties on the part of some of the discussers in comprehending the significance of the range within which the model tests were conducted. The statement set forth the state engineer's basic requirement—namely, that the spillway should be designed to carry a discharge of 80,000 cu ft per sec with a residual, minimum freeboard of 10 ft. The chief engineer (Mr. Howell) and his consultants (W. P. Creager and L. F. Harza, Members, Am. Soc. C. E.) raised the residual freeboard to 15 ft.

A design study based on an assumed discharge coefficient over the ogee section indicated a necessary water surface elevation of 1466—that is, 13 ft above the spillway crest to produce this discharge. The primary purpose of the hydraulic model tests was to ascertain whether the design discharge value would be realized.

It is hoped that this will explain to Mr. Soucek why the tests were not taken to heads of less than 10 ft. The writer agrees with Mr. Soucek that an extension of the tests to lower heads would have been desirable to check, more completely, the conformity between the models. Unfortunately, the necessary time to do so was not available.

The District's studies for the San Gabriel watershed indicate a maximum probable spillway flow of approximately 200,000 cu ft per sec, which is well within the capacity of the spillway. The writer therefore does not agree with Mr. Huber that a larger spillway capacity than the one provided would have been called for, even if a flood such as the one of March 2, 1938, had been on record at the time the revised design was submitted to the state engineer for approval. Had Mr. Huber referred to the diversion tunnel instead of the spillway, the writer would have agreed readily.

Mr. Hickox correctly sets forth the basic equation for the velocity of elemental flow normal to a vertical, cylindrical surface through the crest. However, his statement that three lines having a slope of 1 on 1.5 and different coefficients would represent the points in Fig. 24 equally well is not correct if, as outlined in the paper, such points are neglected which represent conditions affected by backwater. Unfortunately, discharge measurements below the spillway were not made during the March flood of 1938, as there were no facilities for such a purpose. The writer fully agrees with Mr. Hickox that such flow measurements would have been very valuable indeed.

---

[11] Senior Asst. Chf. Engr., Los Angeles County Flood Control Dist., Los Angeles, Calif.

For the interpretation of model tests operating under the influence of gravity only, it is generally acknowledged that the discharge scale varies as the 2.5 power of the length scale. For models operating under purely viscous influences in which gravity plays a relatively small part, it may be shown from Manning's equation that the discharge scale varies as the 2.67 power of the length scale.[12]

In models influenced by both gravity and viscosity, as practically all hydraulic models are, it may be reasoned that the discharge-scale value will be somewhere between the 2.5 and 2.67 power of the length scale, the exact location depending upon the relative preponderance of the gravity or viscosity influence. The primary purpose of testing models at three different scale ratios was to determine the value of this exponent. In model tests made subsequently by the District, and in the model tests reported by the late F. Eisner,[13] results at five different scale ratios could be correlated by the use of the 2.52 power instead of the conventional 2.50. All these experiments deal with overflow weirs having some kind of approach channel. The writer is not yet prepared to specify the power to be used for other models in which both gravity and viscosity enter. However, the points for models of different scale ratios of arbitrary structures are not necessarily satisfied by one and the same equation. It should also be kept in mind that each prototype may be considered a model of a larger prototype.

Mr. Creager offers a substitute for the parabola shown in Fig. 24 in the form of a parabola of the equation $Q = 3.81\ H^{1.5}$. He correctly shows that if these two parabolas have a common point in the 1 : 20 model range—namely, $H = 0.75$ ft and $Q = 2.475$ cu ft per sec—the discrepancy between his parabola and the one shown in Fig. 24 is of the order of 10% for the corresponding points of the 1 : 500 model, as well as for the prototype. For any other point in the 1 : 20 model range, presumably Mr. Creager would compute the coefficient in a similar way and extrapolate to prototype dimensions by the equation he suggests. This is tantamount to accepting the 2.5 power of the length scale as adequately representing the discharge scale factor, and disregarding the results of the other two model scale tests. To the writer, this does not seem justified in the light of the evidence presented.

The revised design of the dam proper, including field and laboratory tests on materials for the rolled rock core section (Zone 3), was prepared in its essentials during a period that preceded Mr. Creager's connection with the District. The success achieved in these tests was due in great part to the assistance and initiative of R. R. Proctor, M. Am. Soc. C. E., and N. M. Imbertson, Assoc. M. Am. Soc. C. E. Subsequently, the revised design of the dam proper, including many additional large and small size tests, was perfected in collaboration with the state engineer and his consultants, and the spillway, outlet works, and appurtenances were designed. In the light of these circumstances, Mr. Creager's reference to a compromise is not clear to the writer. Prior to the completion of the revised design an alternate design was prepared which did not include the rolled rock core section. Instead, similar "grizzlied" quarry material was proposed to be placed by sluicing. Tests were conducted in this connection. They may serve to confirm some of the statements made by Messrs. Jacobs, Feld, and Barona. The material was placed in 25-ft lifts and was thoroughly sluiced at the time of placing. Shafts were then sunk and the material tested at 5-ft intervals in elevation between top and bottom. In spite of the greater care in placing than could be reasonably expected as an average during construction, the dry density of the fines averaged 89 lb per cu ft, and the dry weight of rock and fines averaged 122 lb per cu ft. In comparing these dry densities with those obtained by rolling (122.2 lb for the fines and 144 lb for rock and fines in Zone 3 at the time of placing and on the surface), it is obvious that the two masses are distinctly different in character from the standpoint of stability under saturation, particularly under the influence of earthquake.

[12] "Hydraulic Laboratory Results and Their Verification in Nature," by Herbert D. Vogel, *Transactions*, Am. Soc. C. E., Vol. 101 (1936), p. 597.

[13] "Überfallversuche in verschiedener Modellgrösse," by F. Eisner, *Preussische Versuchsanstalt für Wasserbau und Schiffbau*, Berlin, 1933.

In his interesting and constructive discussion, Mr. Feld raises a question regarding tests conducted in the quarry to ascertain the most suitable quarry methods. The writer was not connected with the District prior to October, 1934. However, records indicate that such tests were conducted by the contractor. According to the specifications, his quarry methods were subject to the approval of the chief engineer. No suitable method was found to produce the rock acceptable under the original specifications in economical quantities.

Mr. Feld also draws conclusions from the cylinder tests, which are supported by the data presented. He further stresses the significance of a feature that is perhaps not generally recognized. It is the breakdown of the grain structure under load. This characteristic for the material in question is particularly brought out in Fig. 14. The breakdown characteristics are extremely important relative to the compaction of a mixture of coarse and fine materials secured from a quarry. Therefore, it would not be a wise undertaking to apply the same design to a dam at a location where this type of rock does not exist. The breakdown effect may become somewhat paradoxical, in that it is at least conceivable, if not practicable, to produce expansion of this type of material in a cylinder with increasing load rather than consolidation. This phenomenon naturally would be in line with the swelling of broken rock as compared to solid rock. Tests on nonsaturated samples resulted at least in relatively large reductions in the void ratio, $e = \frac{n}{1 - n}$, of the fines for relatively small differential settlements. On the other hand, it is obvious that, if such a mixture were unrestricted and were caused to break down into fines of quasi uniform grain size, the volume occupied by such a mass would be larger than the volume occupied by the mixture of course and fine material. A vertical shake-up due to earthquake would tend to do this if the compacted mixture were not restricted by overlying, loose material of adequate weight, such as was provided. A critical void ratio could establish itself as a result of both loosening and breakdown of the grain structure without this provision. Mr. Feld evidently was under the impression that the increment of load in the cylinder which produced the settlement curve, as shown in Fig. 30, was applied at shorter intervals than the increment of load due to the dam fill itself. This was not the case, in that the load increment on the cylinder was actually timed with the load increment on the section of the dam for which the settlement was observed. The discrepancy between the two curves is believed to be due principally to two factors—namely, greater average density (self-compaction) and greater arching effect in the fill.

The writer is duly impressed with the late Mr. Jacobs'[14] exhaustive and valuable contribution. It is hoped that the following supplemental statements will answer his query regarding the analysis of the dam section for earthquake resistance. The dam was divided into two nearly symmetrical parts, relative to its axis. The reservoir surface was assumed at El. 1466 (H.W.S.). Active forces due to static and dynamic water and earth pressures were assumed to be resisted by the downstream prism. The plane of minimum resistance was determined by the *E*-line method.[15] This plane was found to be sloping upward at an angle of 5° 30′ for an average angle of internal friction of 35°. A factor of safety of two resulted, or a minimum average shear coefficient of 0.37. The writer agrees with Mr. Jacobs that the assumptions were conservative. He also agrees "* * * that there is yet much that is elusive, vague, and unknown in the field of soil mechanics" (quoting from Mr. Jacobs' discussion) and it is in part for these reasons that conservatism in respective designs is considered advisable. Mr. Jacobs suggests an interesting and logical modification of the conventional shear formula. The writer shares his concept regarding a decrease of the angle of internal friction with increasing, vertical pressure within normal ranges, so far as damp sand is concerned. This was previously[16] shown by him, based on passive pressure tests.

The final average cost of spreading, sprinkling, rolling, and tamping the material in Zone 3 was 16¢ per cu yd. The roller combination that proved most economical during construction was one double drum, loaded with sand and water to a weight of approximately 24 tons. Five of these units were used. An average of four forward and four backward, or a total of eight, passes for each strip of compacted material was necessary. Mr. Jacobs' difficulties in accounting for the penetration resistance and shear coefficient relation as shown in Fig. 20 are perhaps due to overlooking the statement that the curves are "purely theoretical." They were derived from two independent, experimental relations—vertical pressure versus shear coefficient, and penetration resistance versus vertical pressure. There does not seem to be a definite relation between penetration resistance and shearing strength, possibly due, in part, to the "personal equation" as suggested by Mr. Jacobs. Since the completion of the dam, the reservoir has been full, or nearly so, twice, and in the intervals the dam has been under considerable water pressure for several months at a time. Nevertheless, to date (June, 1942) there has been no measurable seepage through the dam.

---

[14] Mr. Jacobs died on March 16, 1942.

[15] *Transactions*, Am. Soc. C. E., Vol. 100 (1935), p. 719.

[16] *Ibid.*, p. 791.

In comparing the San Gabriel Dam No. 1 with a similar dam in Mexico, Mr. Barona reveals some features of interest. Among these is his reference to the use of smooth rollers for the compaction of gravel-sand-clay mixtures. Such a mixture is quite different in character from the one used in Zone 3. It is primarily an earth fill with a dissimilar material (gravel) embedded in it. Definite contrasts always remain between the two. In contradistinction, the material used in Zone 3 "fuses" into a quasi homogeneous mass. The contrasts between rock and fines disappear and with them the surface friction phenomena. The latter material could not be adequately compacted with a smooth roller. The writer would have welcomed data on embankment settlement of Mexican dams for comparison with Fig. 30. Mr. Barona's reference

to soil concrete merits attention. However, much research is required before knowledge of soil concrete equals that of compaction.

The question of stresses and their distribution in dam embankments has been much debated. The writer is satisfied that present knowledge of soil properties is inadequate to justify refined, mathematical analyses, based on stress functions such as are applicable to monoliths for the usual type of embankment. On the other hand, relatively simple and accurate stress analyses can be made if it is reasonable to treat an embankment section as a monolith, the criterion being whether or not the stress condition so obtained is possible within the strength of the material and the boundary conditions of the section. Based on the known properties and the elastic behavior of the dam under maximum and minimum load before, during, and after, the March flood of 1938, it is believed that Zone 3 acts as a monolith by virtue of its density and

FIG. 36.—EXTENSION OF STRESS ANALYSIS FROM FIG. 35

rigidity, which are much greater than those of the loose rock and of the prestressed (compressed) condition due to surcharge. The analysis is shown in Figs. 35 and 36 for:

(*a*) Water penetration to the upstream face of Zone 2 only;
(*b*) Water penetration (percolation) through the section as in Fig. 32; and
(*c*) Zone 3 unloaded (initial condition).

Referring to cases (*a*), (*b*), and (*c*), the stresses are marked with the indexes 1, 2, and 0, respectively. Normal σ_x stresses were determined in the usual manner for the first two cases, and the σ_y, τ, and principal stresses at the upstream face (point *A*) with the aid of Mohr's circle.[17] In a triangular section under triangular load the stress distribution is linear. Hence, the shearing stress may be determined at the downstream face (point *B*) to satisfy the requirement that the sum of all horizontal forces must be zero. Principal stresses may then be determined for any point along the base. The third principal stress (σ_{III}) at point *B* must, as a boundary condition, be within the active pressure of the surcharge.

In case (*b*) with percolation through the dam, the stress distribution is affected by buoyancy and water pressure within the section. Point *C* merits attention because of increased shear. An angle of internal friction, $\phi = 40°$, is believed conservatively representative for Zone 3 material. The analysis shows that this stress condition is possible, in that there is no tension in any direction and shearing stresses are well within the shearing strength.

In case (*c*) the rupture plane and point of maximum shear, *D*, were determined by the *E*-line method.[18] In this case the normal σ_x stresses are proportional to the height of the section, and the shearing stress at *D* exceeds the shearing strength. The fact that sections with much steeper slopes of this material actually stood up under complete saturation and even wave action without the slightest sign of weakening would tend to make the assumed angle of internal friction of 40° appear decidedly conservative.

In conclusion, the writer wishes to express his appreciation to the discussers for their valuable additions to the paper. As the project engineer, he naturally had close contact with the office and field personnel engaged in the work. He regrets having been unable to do better justice to their outstanding work. It will always be remembered with respect and gratitude.

SALVAGE OF SEWAGE

FINAL REPORT OF THE JOINT COMMITTEE OF THE SANITARY ENGINEERING DIVISION AND THE IRRIGATION DIVISION ON THE SALVAGE OF SEWAGE

General Statement and Summary

Consideration is limited in this report to the direct salvage of products from sewage—water, fertilizer, gas, grease, and such other materials as may be separated from sewage in the treatment plant or elsewhere and used. It does not include consideration of such salvage as may occur after the sewage leaves the collecting system or disposal works and, mingling with the waters of streams, lakes or underground strata, is again put to useful service. Factors limiting the study are arbitrary and were adopted by a majority vote of Committee and Subcommittee members after an extended period of investigation had indicated that any wider view would involve consideration of many topics which might better be subjects for separate reports.

Public Health Considerations

The utilization of products salvaged from domestic sewage should be with a full realization of the public health significance of such use. The potential health hazards incident to the utilization of the salvaged products will, to a varying degree, modify their usage.

Standards for the use of sewage and its by-products promulgated by health authorities afford the best criteria in this field, and in general imply that:

(*a*) Raw sewage, or its untreated solids content, or the soil which it has recently irrigated shall not come in contact with foodstuff designated for human consumption; nor shall live stock graze upon pasture irrigated therewith;

(*b*) Forage crops which are to be harvested and cured may be irrigated with the untreated effluent from adequate subsidence tanks;

(*c*) For use in the cultivation of human foodstuff, particularly that to be eaten raw, the water reclaimed from sewage must be well oxidized and thoroughly sterilized at all times; and (*d*) Sewage solids to be used as fertilizer must be digested and dried, or if undigested may be kiln-dried at temperatures which will destroy all inimical pathogenic organisms.

SEWAGE

Sewage is a heterogeneous combination of organic and inorganic, suspended, colloidal, and dissolved solids dispersed in large quantities of water. Principal among items of potential value to be salvaged therefrom are water, fertilizer, gas, and grease. It contains many other constituents but usually in such small quantities, or so cheaply obtained from other sources, as to render their salvage from sewage uneconomical.

Sewage characteristics vary widely in different localities. The effect of water abundance, customs of the citizens, industrial development and whether separate or combined sewers are in use, are reflected in the general per capita contribution to the sewers, which will vary from 30 to 200 gal per capita daily (G.C.D.). Solids contribution will vary from 0.1 to 0.3 lb per C.D.

Water.—In the more arid West, where irrigation is practiced extensively, and where reclamation of water from sewage assumes a greater importance than elsewhere, the average daily flow in separate sewers is usually less than 100 G.C.D. and will average about 65. Among others, a notable example to the contrary is the City of North Yakima, Wash. (1),[1] where, because of the rise of ground water during the irrigation season, the flow increases from 100 G.C.D. in the winter to 530 G.C.D. in the summer. The quantity of water recoverable from sewage is substantially equal to the entire sewage flow.

Fertilizer.—A survey in 1924 (2) indicated throughout the United States an average solids contribution to the sewers of 0.24 lb per C.D. Wide variation from this average will depend upon whether or not the area served is industrial in character, as well as the character of the industries and their periods of operation. Certain types of industries (notably packing houses, breweries, distilleries, and the like) will contribute a reasonably high uniform load throughout the year; whereas others—such as wineries, fruit-canning establishments, and vegetable processing plants—produce large volumes of solids for comparatively short periods and no solids for the remaining months.

The grade of fertilizer obtained from sewage solids will depend upon the preliminary treatment afforded the sewage and processes involved in sludge treatment. Dried activated sludge is highest in nitrogen, ranging from 3% to 6%, and generally averaging more than 5%. During the process of digestion, sewage solids will lose about the same percentage of nitrogen as of organic material (3*a*), and sludge digested to a 50% reduction in organic material will range from 1.5% to 3% nitrogen, depending upon its original composition, and will average about 2%. Phosphoric acid is found in sludges in concentrations from 0.3% to 4% and averages about 1.5%. Potash, present in dried activated sludge in concentrations usually less than 1% (4) (16*b*), is absent from digested sludge. Dried activated sludge will range from 60% to 70% organic material. Sludge is considered well digested when the organic material is about 50% consumed (5), although this figure may be exceeded at times; therefore digested sludge will range from 45% to 55% organic material. Digested sludge which is being prepared for fertilizer will seldom run less than 50% organic.

---

[1] Numerals in parentheses, thus (1), refer to corresponding numbers in the Bibliography.

Nitrogen lost from the sludge during the digestion period is to be found in the form of ammonium bicarbonate in solution in the sludge liquor (3*b*), whence it may be recovered as ammonia or ammonium sulfate by distillation or by treatment with zeolite; or it may be recovered as magnesium ammonium phosphate by evaporation with salt works bitterns and mono-calcium phosphate (6). Its recovery is not deemed economical at this time, although production of the phosphate salt holds fair possibilities.

Gas.—Methane gas, a product of the anaerobic digestion of sewage solids is of value as a fuel in internal combustion engines and heat generation (7). Per thousand cubic feet of gas, composed of two thirds methane and one third carbon dioxide, about 55 lb of organic sewage solids will have been consumed in the digestion tank. The current prices of gas and fertilizer in the area under consideration will be factors in determining whether the solids are more valuable in the form of fertilizer or gas, and thus will help to decide the most appropriate method of sludge disposal. In general, the sludge will have more potential value as fertilizer than as gas, except in localities where artificial gas of low calorific value is used exclusively.

Grease.—The grease content of sludge from domestic wastes varies widely. Grease recovery from combined domestic and industrial wastes, or from their sludges, is not deemed an economical venture in the United States at this time because of the abundant supply of cheap greases from other sources. Extracted, the grease from sewage is usually found to contain considerable inorganic oil from which it must be separated before it becomes of much value as a commercial product (8) (9) (10). Direct recovery of grease from wool-scouring and packing-house wastes offers more advantages than its recovery from sewage.

Other Constituents.—Recovery of organic acids from supernatant liquor during acid fermentation of sewage sludges is a possibility (11), although with the abundance of organic acids cheaply produced commercially it cannot be considered economically feasible.

There is some possibility of re-use of ash following incineration of sewage sludge. Added to the raw sewage, its lime content may aid coagulation of solids. If it is high in iron, that metal may be leeched out with sulfuric acid to be re-used as a coagulant. The use of ash for filling low-lying land may assume importance in certain areas.

PUBLIC HEALTH CONSIDERATIONS

> "An important factor in epidemiology is the longevity of pathogenic bacteria in nature, for upon such longevity rests the ability of various agents such as foods, to disseminate communicable diseases. Chief among such agents may be fresh vegetables which are eaten raw" (12).

Recognition of this has caused health officers almost without exception to view suspiciously the use of sewage or sewage sludge in crop culture, and notwithstanding that the evidence upon which to base hygienic misgivings is contradictory, official prejudice persists (13). Left to the mandates of health officers, it is unlikely that the use of water reclaimed from sewage, unless clear, well oxidized, stable, and sterile, would be permitted for the irrigation of vegetables consumed raw, or that sewage effluents of any character would be permitted to be so utilized as to threaten contamination of domestic water supplies. Their attitude toward the use of sewage sludge would be more tolerant as a rule, permitting heat-dried activated, and sun-dried or heat-dried digested, sludge to be used on garden vegetables other than those to be eaten raw, but excluding from any consideration in crop culture the use of raw sewage solids (13).

There is ample evidence to indicate that pathogenic bacteria to be found in nearly all domestic wastes will persist for days in sewage-irrigated soil (12), as well as upon the outer skins and leaves of vegetation grown therein; and under such a wide variety of conditions as to appear to render inevitable their transmission to those working in the soil or handling and consuming the produce therefrom. Despite the fact that evidence tracing epidemics to such sources is tenuous and inconclusive in many of the instances which have been the subject of epidemiological investigation, Fred W. Tanner concluded, in 1935 (12),

> "Good epidemiological evidence seems to exist in the literature to the effect that fresh vegetables may and have caused communicable diseases and that the sanitary condition of the soil from which they are harvested is important."

He then cited twelve examples which indicate the possibility of communication in which three seem to offer conclusive evidence, tracing epidemics to sewage-contaminated green vegetables. Mr. Tanner states further:

> "The review of literature indicates quite clearly that fresh vegetables which are raised on polluted soil may transmit pathogenic bacteria. The increase of typhoid fever every year in Paris during July to October was attributed to fresh vegetables harvested from sewer farms."

The Paris report states (14) that during the summer at the time the paper was written in 1923, the incidence of typhoid fever in Paris, France, increased markedly from July to October due to the fact that many Parisians summered in the environs of Paris and consumed polluted water, and that the increase of disease among those citizens who had not left Paris could undoubtedly be traced to carriers; and possibly to the use of sewage-polluted green vegetables which investigation disclosed were being raised in large quantities upon the sewer farms of Paris. The article stated that farms were established to be used for pasturage, but proximity to the city afforded a great incentive to raise vegetables, including among others, lettuce, dandelion greens, endive, onions, parsley, and radishes, which were the subject of epidemiological investigation in attempting to account for the high incidence of fever among citizens. Commenting upon this and other situations, in letters to the Committee, E. A. Reinke, Assoc. M. Am. Soc. C. E., senior sanitary engineer of the California State Board of Health, stated in part: "It appears from the public health aspect that we have far more suspicion than fact to guide us. Epidemiological studies are rarely absolutely conclusive." According to Dr. E. N. Chapman (15):

> "It has been shown
>
> (1) That gross pollution with sewage of some of our streams used for irrigation of vegetables exists in Colorado.
>
> (2) That this contamination of irrigation water offers an ideal method for the spread of filth diseases—typhoid fever, amoebic dysentery and infectious diarrhea—since these conditions are transmitted by human excreta.
>
> (3) That there is an epidemic each year of diarrhea by the time the bulk of vegetables raised with contaminated water comes upon our markets."

Despite the fact that Dr. Chapman's evidence is about as conclusive as any regarding the spread of communicable diseases by sewage-irrigated vegetables, inspection indicates that in Denver, Colo., where a large portion of the vegetables irrigated with sewage-polluted water from the South Platte River are used, the average annual death rate throughout the growing season, from typhoid fever and from diarrhea and enteritis, is equal to or less than the average for the United States; which may be construed as evidence to the effect that the increase in the incidence of these diseases in Colorado may not be the result of transmission by green vegetables shipped to the city, but rather from drinking sewage-contaminated water in the rural area.

Referring to the extensive Berlin sewage farms in Germany, H. J. N. Hodgson states in part (16*a*): "Bacteriological tests are made at intervals on the milk, cheese, vegetables, etc., produced at the farm, with no positive evidence of the presence of bacteria indicative of contamination by sewage," and in an excellent review of current knowledge upon the hygienic aspects of the use of sewage sludge, the Committee on Sewage Disposal with the American Public Health Association states in part (17*a*): "Obviously the index of the danger of using wet sludge or air-dried sludge for the growth of crops must lie in the evidence of experiments to determine the life of pathogenic organisms contained therein and of experience where such material is used." Thus the potential danger is coupled with experience to indicate the menace in the unguarded and unwise use of these sewage products.

Investigation indicates that there is much evidence that bacteria do live for many days and under a wide variety of conditions; but experience discloses that it has been thought unnecessary to investigate more than comparatively few instances in which reasonably positive evidence can trace epidemics to the use of sewage or sewage sludge in crop culture (13). From a canvass of state sanitary engineers in 1937 it was learned that in sixteen states they advised against the use of sewage sludge on garden crops or did not permit it (17*a*). Evidence of eight national authorities pointed to the fact that no harm should result if the sludge is properly processed and used with discretion. The conclusions of Langdon Pearse, M. Am. Soc. C. E., upon this phase of his investigation were as follows:

> "From the hygienic standpoint, heat dried activated sludge and heat dried digested sludge appear safe for any reasonable use in agriculture or

> horticulture. Digested sludge, air dried, appears safe for such purposes if used like manure and plowed in when preparing for a crop; and if care is taken not to apply such sludge thereafter on root crops or low-lying leafy vegetables which are eaten uncooked. Thorough digestion and air drying, as well as storage of the air dried sludge afford a sufficient protection. The Committee knows of no case of sickness traceable to the use of digested sludge or activated sludge" (17*a*).
>
> "Fresh sludge should be regarded as only one degree removed from night soil and treated as such, being used only on forage crops and then applied and plowed in promptly thereafter" (17*b*).

In 1934 the directors of public health in each of the forty-eight states and the District of Columbia were requested for information relative to the extent of sewage use for irrigation in each of the states (13), the influence of such use on the public health, and the standards which should be prescribed and enforced if water and fertilizer reclaimed from sewage are to be used in the production of foodstuffs (*a*) to be eaten raw; (*b*) to be cooked; (*c*) to be used as fodder crops, or on public grounds. The questionnaire also sounded out the attitude of state health officers toward the use of reclaimed sewage products. Thirty-nine states and the District of Columbia replied. Of these, nine admitted having had experience with sewage irrigation and sewage irrigated crops; four were able to trace illness of an epidemic order to such use, whereas one other stated that cattle, pastured on a raw sewage irrigated field, developed poorly and were infected with cysticercus bovis.

The celebrated instance of the development of teania saginata from eating beef infested with cysticercus bovis which had pastured on the raw-sewage irrigated farm of Melbourne, Australia, is further substantiation of the general danger (18). In this instance, the cattle, which at one time were sold for beef for human consumption, greatly reducing the cost of operating the sewage farm, were forced out of the market and could thenceforth be used only for purposes other than human consumption. In the nine states where sewage irrigation was or had been practiced, the attitude was one of tolerance for the act and rigid regulation in the production of the effluent as well as the nature of the crops for which used (13). Only one of the nine was agreeable to the use of treatment plant effluent on vegetables to be eaten raw; however, in this instance, the standard prescribed was such as to render the effluent the substantial equivalent of potable water. Thirty states reported that there was no sewage irrigation within the borders. A number of these declined to express any opinion about the measure, and seventeen would not tolerate its use. Many found the idea of sewage irrigation repugnant.

More than half of the state officers without experience in the use of sewage sludge would prohibit its use in any form on vegetables or fruits to be eaten raw (13). A number indicated repugnance to the idea, without expressing any definite knowledge of the hazards. Opinion was about equally divided for and against the use of sewage sludge on vegetables to be eaten cooked. The majority expressed a willingness to use it on fodder crops and as a fertilizer for lawns and parks. Wells A. Hutchins states (19*a*):

> "Notwithstanding the fact that raw sewage was being applied to crops in some localities in 1937, the practice has little support among public

> health authorities. It is generally considered hazardous, and therefore is either definitely prohibited or at least discouraged by the state officials."

At a given time sewage may, or may not, contain pathogenic organisms. "In case of illness, particularly in epidemic form, among the inhabitants contributing to the flow, the sewage may carry large quantities of such organisms not otherwise disposed of by direction of the public health authorities" (19*a*). The ever-present possibility of such occurrence is considered by health authorities to render untreated sewage a potential source of infection. It is appreciated that raw sewage has been used for irrigation for many years, in many places, both in the United States and abroad, and that evidence of ill results is generally absent or not conclusive. Nevertheless, the hazard exists, and its perpetuation is not in the public interest (19*a*).

For the purpose of regulating the use of sewage water and its solids for irrigation, the states in which irrigation is practiced have adopted legislation which grants executive authority to public health officers (19*b*). Health officers in western states are not all endowed with the same degree of authority in coping with the problem. California has defined its position most clearly and has described sewage fertilizers and effluents to be used in irrigation under a wide variety of conditions (5). In the remaining western states regulations vary from the implications of the Montana law that the sale of all vegetables grown on farms irrigated with human sewage is prohibited (19*b*), to that of Oregon, where no formal regulations have been issued, and of Texas, where the Department of Health acts in an advisory capacity only. National legislation respecting the use of sewage irrigation is not at all comprehensive. Regulations promulgated by the Secretary of the Treasury prohibit the movement in interstate commerce of articles known to have been exposed to infection by certain disease organisms (19*c*), and, upon occasion, the United States Public Health Service has cooperated with state and local authorities to prohibit shipment of vegetables known to have been irrigated with sewage or with water containing large quantities of raw sewage.

There seems little doubt that the presence of pathogenic bacteria will persist in raw sewage, or ground contaminated therewith, for many days (12), and that under the circumstances there is danger of the spread of contamination through the use of vegetables grown under such conditions, particularly if eaten raw. It has been reasonably well determined, however, that water of such purity and freedom from bacterial contamination may be reclaimed from sewage as to be fairly safe for use in irrigation; and it is also demonstrable that sewage sludge undergoing digestion for a period of ten days or more is quite free of pathogenic bacteria causing intestinal diseases, although the cyst of the amoeba has been discovered in well-digested sludge (20).

As in the activated sludge process, oxidation, followed by disinfection, should produce an effluent which is the bacteriological equivalent or superior of many irrigation supplies, although no sterilization process is current today which is 100% effective against the dysentery amoeba (21) (22). In his investigation of sewage irrigation as practiced in the western United States, Hutchins states in part:

> "From a sanitary standpoint it is theoretically true that any kind of irrigation water that does not meet the recognized bacterial standards for domestic water is a potential source of danger. As a matter of fact, however, in no instances in the present study, have epidemics been traced definitely to irrigation with sewage in which the Bacillus coli content has been substantially reduced, even though the standard of drinking water was not attained; and in only a few cases have individual cases of illness been suspected of coming from such sources" (19*d*).

Thus it would appear that, except for use upon vegetables or fruits to be eaten raw, an effluent from about the treatment afforded by subsidence, trickling filters, and secondary subsidence effecting about 85% reduction in bio-chemical oxygen demand (B.O.D.) and suspended solids, followed by chlorination, should satisfy health requirements, and that the use of reclaimed water for irrigation of growing crops—as well as of processed sewage solids as fertilizer—may not be ruled out on strictly public health grounds.

THE RECLAMATION AND USE OF WATER FROM SEWAGE

For What Purposes Used.—In some cases, water reclaimed from sewage is adaptable for industrial and irrigational usage. There are no known instances in the civilized world where a direct reclamation of water from sewage is used to supplement a domestic supply, although there are many underground strata which receive some measure of repletion from the drainage of cesspools and from rivers carrying the discharge of sewage treatment plants, and otherwise. It is also a fact that many grossly sewage-polluted streams are used as raw water supplies of cities in the United States and other countries, this report is confined to direct reclamation or re-use of products from sewage; further discussion will therefore relate to the use of reclaimed sewage water for industrial and irrigation purposes.

Chemical Limits of Good Irrigation Waters.—The usual limiting constituents in irrigation water are sodium, carbonate, chloride, sulfate, and boron (23) (24) (25) (26). It is generally conceded as desirable to have the ratio of sodium to sodium-plus-magnesium-plus-calcium less than 0.6, although many crops are irrigated where ratios are much higher. It is also desirable that water for irrigation use have a sulfate content less than 200 ppm, and a chloride content less than 150 ppm, although there are waters used for irrigation purposes in western states with sulfate contents in excess of 550 ppm (27), and chloride contents of more than 700 ppm. Another general requirement for satisfactory irrigation water is that the total salinity shall be less than 1,000 ppm. In contradiction to this, waters are used containing 3,000 ppm (27).

The effect of boron in irrigation water has been given particular attention in California. Boron is found to be essential to the development and growth of nearly all plants, but becomes toxic to most plant life if present in concentrations greater than a few parts per million. Critical concentrations of boron in irrigation water used for lemons, walnuts, avocados, and some other tropical crops is from 0.5 ppm to 1.0 ppm, whereas the tolerance of many other crops is much higher (26).

In the analysis of water reclaimed from sewage, particular attention must be paid to the salt concentrations, which, without exception, will be greater than in the original water supply, although not necessarily greater than those tolerated by, or of benefit to, growing crops. From a number of sewage treatment plants in the West, including some from which sewage effluents are used for irrigation, it is found that boron varies from the tolerance applicable to citrus and other types of tropical trees to concentrations much higher (26). Fruit-packing establishments, where borax is used in washing fruit, are at times responsible for excessive concentrations of boron in sewage. Other sources may be found in the widely divergent applications of various forms of borates in industry and domestic use.

In his report on the "Analysis of Ten Sewage Treatment Plants in California," Hutchins states (19*e*) in part:

> "Chlorides were well on the safe side. As to percent of sodium, the result from one city showed half the samples contained 60% or more and most of the remainder above 50%. The critical ratio is considered to lie between 50 and 60%."

Effect of Harmful Salt Concentrations in Irrigation Water.—Irrigation experts are agreed that some of the irrigated lands in western United States have suffered from excessive concentrations of toxic salts in the soil, rendering the ground less friable and productive than when irrigation was first practiced in the area. This results from the base exchange qualities of the soil itself and over concentrations of sodium in the water tending toward the exchange of sodium for calcium and magnesium with resultant high concentrations of the dense sodium salts in the soil. In addition, indications are pretty strong that where water pumped from under the land being irrigated tends again to reach the same source of supply, carrying with it its additional burden of salts, the point of toxicity is reached more rapidly.

If the practice of irrigation with water, deemed unsafe because of salt concentrations (excepting boron), is continued in western United States, there appears to be little, if any, reason for excluding the water content of sewage for such purpose. If it is not to be used, the reason must ordinarily be found otherwise than in its concentration of salts or its unbalanced sodium radical.

Beneficial Salts in Sewage.—Sewage water contains certain valuable plant foods in solution, notably nitrogen, boron, phosphoric acid, and potash, in proportions which may render it more valuable for crop culture than other irrigation supplies. A million gallons of average effluent from plain subsidence may add as much fertility to the soil as two tons of ordinary barn manure, provided the water is used wisely and not as in ordinary farm procedure (29). The value of the salts contained in sewage water has more often than not been lost because of the heavy applications of water to soil required for disposal during the growing season as well as its continued abundant application when no crops are being raised (30). The net result of such procedure is to carry most of the dissolved salts through to the subsurface drainage, and the soil may actually suffer impairment. It is essential that the farm be operated primarily for crop production and not for sewage disposal if the benefits to be derived from the dissolved salts are to be secured.

Pathogenic Implications.—Water used for irrigation should be reasonably free from disease bacteria, and the best of bacteriological standards should be enforced in the use of sewage effluents where irrigation water may be cross-connected with other supplies or mixed with an otherwise reasonably pure irrigation supply from which domestic water is at times drawn by irrigators and their help. Hutchins states in part (19*d*):

> "As a matter of fact, however, in no instances in the present study have epidemics been traced definitely to irrigation with sewage in which the Bacillus coli content has been substantially reduced even though the standard of drinking water was not attained; and in only a few cases have individual cases of illness been suspected of coming from such sources."

This statement is limited not only to the irrigation of fodder crops and of vegetables to be eaten cooked, but also to irrigation with effluents from subsidence tanks of vegetables and fruit to be consumed raw.

From the standpoint of existing facts, it would appear that bacteriological standards for irrigation waters to be used without restriction might be drawn without reference to those of drinking water, and that sewage effluents from about the quality of treatment imposed to reduce the biochemical oxygen demand and suspended solids from 85%, followed by chlorination to a residual, should be adequate although esthetic considerations might reject this view. It should also be clear, that sewage effluent need not be ruled out of the irrigation scheme because of its bacterial content when the latter has been substantially reduced from that of raw sewage.

Incentives for Irrigation with Sewage.—Irrigation for crop culture is practiced extensively in the eleven western states of the United States (30). Three or four large irrigated tracts extend easterly into neighboring states, but for the purpose of an analysis of the utilization of sewage water for agriculture, the statistical data gleaned from an examination of the eleven western states and the arid, less populous, southwestern strip of Texas, serve to illustrate the picture clearly enough. Eastern and Central United States depend upon rainfall; irrigation is not practiced.

The area under discussion is peopled with approximately twelve and one-half million individuals, of whom more than six million reside either in tidewater metropolitan areas along the Pacific Coast, where sewage flows are discharged directly into the sea, or in areas where ample rainfall precludes the need for irrigation (30) (31). Of the remaining six and one-half million, about four million reside in cities which are sewered and in the environs of which irrigation is practiced. Therefore, in the collected sewage of these states there exists an available supply of irrigation water, in the form of sewage, approximating 300 mgd which, assuming a maximum month's demand equal to 30% of a total yearly demand of 3 acre-ft per acre, might, without storage, be utilized to irrigate about thirty thousand acres of land. In passing, it may be mentioned that the irrigated area in western United States, now under cultivation or in immediate prospect of cultivation, is nearly twenty-three million acres.

Of this 300 mgd a considerable proportion is, in fact, now being utilized as irrigation water after mingling with stream water into which it is discharged for disposal. Some of it, however, is wasted into streams from which it is not again taken for re-use and is, therefore, lost for irrigation purposes. Sewage from the City of Denver is a material contribution to the South Platte River, the entire summer flow of which, including the sewage of Denver, is at times diverted for irrigation use. To the contrary, it cannot be said that, to date (1942), sewage reaching the Columbia River through its tributaries, the Snake and Spokane rivers, has been a contribution to irrigation water. Probably 40 mgd are lost by being wasted into streams from which the water is not recovered for irrigation; of the remaining 260 mgd, about 100 mgd reach streams or underground waters from which they are again taken for re-use in irrigation.

Thus, eliminating:

(*a*) Seaboard cities;

(*b*) Those cities which are located in areas not using irrigation water;

(*c*) Cities from which the sewage is carried away by streams not utilized for irrigation waters; and

(*d*) Cities, the sewage of which is reclaimed from streams and the like and re-used—

there remains for potential irrigation use about 160 mgd of sewage which are sufficient, without storage, to provide annual irrigation water for about sixteen thousand acres of land.

Not including those areas which derive irrigation water from streams, the waters of which contain sewage or sewage plant effluent, there are about ten thousand acres of western land, four fifths municipally owned and two fifths municipally operated, which are irrigated with sewage or the effluent from municipal sewage treatment plants. Scattered about among the seven hundred million acres of arid land west of the one-hundredth meridian, there are, therefore, some six thousand acres of land to which the practice of sewage water irrigation might be economically extended if sufficient incentive were present. Of the seaboard metropolitan areas, only those of California are located in, or close by, extensive irrigated farm sections, and from the California cities the sewage of Los Angeles looms largest in offering a possibility of exploitation for irrigation use.

The incentives needed to make direct irrigation with sewage either popular or much of a success appear to be lacking. There is no great need of additional irrigated lands in western United States or for the fertilizing qualities of the solids in suspension or solution in sewage. Neither of these needs or desires exist to the extent that objections and restrictions to the use of sewage in crop culture are readily surmounted. The burden of proof that irrigation with sewage is not objectionable from the standpoint of health hazards, violation of esthetic standards and general cleanliness is placed on the sewage irrigation practice by health authorities and by those who are expected to consume the sewage irrigated crops. The net result of this is that with but few minor exceptions, sewerage works in the United States have not been planned to take account of crop culture with plant effluent as a source of revenue.

A fact which mitigates against the reclamation of water from sewage and its application in oxidized and disinfected form directly to crops is that, generally, irrigation water is not relatively expensive where sewage flows exist or are abundant. This follows logically from the fact that cities in the western irrigated land were established, almost without exception, where irrigation was easiest and consequently where water rights and rates are today based upon early appropriation of inexpensive irrigation supplies. In its flow from the city, sewage travels downhill, usually toward water that is even less expensive. Uphill and away from the place of concentration, cost of water may be considerably higher, particularly so if it is pumped or if it has been brought to the land through the construction of costly hillside ditches or as a result of expensive water storage. If the sewage is partly treated and transported to such an area, the cost involved in treatment, transportation, and segregation from other water supplies which it might be expected to contaminate, constitutes an item that almost invariably makes this water more expensive than the water applied to neighboring farms.

The reclamation of sewage water and its use in agriculture probably has a better chance of success in the metropolitan area of Los Angeles, Calif., than anywhere else in the country. Los Angeles County is arid, notwithstanding which it is the richest county, agriculturally, in the United States. Prices paid for irrigation water to raise the valuable citrus and other crops would be prohibitive elsewhere. Although potentially productive arid lands lie fairly close to the municipality, reclamation of sewage water, and its application to the soil, does not appear a safe economical venture.

In the metropolitan area of Los Angeles, there are two small activated sludge plants and one trickling filter plant producing effluents which, under existing rules, may be used for limited crop culture. A group of four cities operates an activated sludge plant close to the city limits of Los Angeles, from which the effluent, amounting to about 8 mgd, is discharged into a near-by wash to be diverted later for irrigation use or to sink into the water-bearing sands below. With but these and one or two other minor exceptions, the sewage from the entire metropolitan population—more than 2,500,000—flows to the sea.

Many schemes have been proposed for using the fresh-water component of this 125 mgd of sewage in agriculture and industry; however, all fail to receive public support because they cannot be made to indicate a return commensurate with the proposed expenditure, to say nothing of the many complications attendant upon exchanges of water, separate systems of distribution, legality of water diversion, governmental and financial structures, and general public disapproval of wholesale sewage water irrigation of farm produce.

Barring the fact that the case for Los Angeles is complicated by the complex structure of its political and social life, it is the counterpart of sewage irrigation attempts elsewhere in the West. Lacking the elements of good business, it is not probable that sewage irrigation will become a very important consideration except as a means for sewage disposal.

Public Attitude.—In any use of sewage water for irrigation, the public attitude is a factor with which to reckon. Quoting Hutchins (19*f*):

> "Aesthetic considerations are important in that they may, and sometimes do, affect the market for produce from sewage irrigated farms. The

> direct applications of polluted water to vegetables which may be eaten uncooked is not only objected to by sanitary authorities, but is obviously repugnant from an aesthetic standpoint. In case of vegetables always eaten cooked, regardless of whether the danger of infection is minimized or entirely removed by the cooking, aesthetic objections to the bringing of such foodstuffs into the kitchen remain on the part of many people. The same considerations apply to low-growing small fruits, such as strawberries, which remain close to or in contact with the ground. If many consumers in a given area have such objections, the marketability of vegetables grown commercially may be impaired and the result may extend to many food products from the same general locality."

It is doubtful that edible products of sewage irrigation could long be sold unless prepared for eating before being brought into private kitchens, and there is considerable doubt even then that there would be a ready market for such foodstuff if its origin were known. Were the source concealed and the crop culture carefully supervised and controlled by health officers, it is altogether likely that no nuisance or menace to public health would ensue—from which it develops that action taken to disclose the origin of the irrigation waters would be a potent factor in the sale and use of such produce even though it might not be readily ruled out on the score of public health menace.

Sewage Water Rights.—Sewage water rights are at times important factors in the use of sewage for irrigation (19*g*) (32) (33). Laws regarding the rights to re-use water which has served the purpose for which originally appropriated are not alike in all states. Under judicial ruling it is possible in some states to re-use the sewage if such re-use is had before the sewage enters a natural stream, whereas in others the right of the original appropriator extends to ownership of the sewage even after it has mingled with other waters. In still others, ownership ceases once the diverted water has become sewage and the latter may be taken by another appropriator whose right to diversion may not be disturbed.

Three cases which serve to illustrate are found in Colorado, Wyoming, and Washington. In Colorado it has been held by the State Supreme Court that a city does not own its treated sewage; that once it becomes spent water—having served the use for which it was originally diverted or appropriated—it becomes public property. The City of Cheyenne, Wyo., was permitted to dispose of its sewage to an irrigator by contract, but lost ownership if the sewage was permitted to mingle with stream water in the natural water course from which originally diverted. In correspondence with the Committee, S. A. Greeley, M. Am. Soc. C. E., states that Walla Walla, Wash., was permitted to change the character of effluent from its treatment process but was compelled to locate its plant so as not to disturb prescriptive rights established by an appropriator who diverted the sewage for irrigation use.

Summarizing, it may be stated, with respect to the reclamation of water from sewage for irrigation purposes, that its use is probably not greatly restricted by salt content other than if it is heavily impregnated with boron, but rather because of the possibility of transmission of disease unless adequate treatment is provided. Incentives for irrigation with sewage are almost totally lacking in western United States because of the high relative cost of reclamation of sewage water and the relatively insignificant acreage which may be reclaimed.

Furthermore, the attitude of the public toward sewage irrigation, particularly with respect to the esthetic considerations involved, tends to exclude sewage irrigated crops from competition with those raised with fresh water. These are the potent factors that will probably limit the use of reclaimed sewage water for irrigation in the United States for many years.

USE OF RECLAIMED SEWAGE WATER IN INDUSTRY

The quality of water to be used in industry depends in each instance upon the service the water has to perform. At times water is used simply as a mechanical means to transport substances or material from one part of a manufacturing process to another. In others, it may be used for boiler purposes; while again, it may enter directly into the manufactured product. Cooling and condensing offer a wide use for water in industry.

It is difficult to imagine any circumstance where water entering directly into a manufactured produce would be reclaimed from sewage. In general, such waters would be used for canning purposes, brewery waters and soft drink bottling, motion picture industries, and the like. It is likewise extremely unlikely that reclaimed sewage water could be used without extensive treatment and assurances in the meat products packing industry or in the transportation of fruit and vegetables from one portion of a plant to another. Furthermore, as a means of preventing the spread of water-borne disease through infection, it is unlikely that anything in a manufacturing process, which would need to be handled wet by those engaged upon the job of manufacturing, would be transported by sewage water through flumes. These would include such products as sugar beets, oranges, sugar cane, and allied materials—in fact, almost anything except waste product from sawmills, cabinet manufacturers, and the like. It seems a little incredible that sewage, or water reclaimed from sewage, could find any place in industry except possibly as boiler feed or cooling and condensing waters. The Committee, after due consideration, has concluded that only the latter uses are to be considered in this report.

Water for Boiler Feed Purposes.—In boiler feed water it is desirable to have water practically devoid of calcium, magnesium, carbon dioxide, and free oxygen; sodium chloride should not be present in concentration in excess of 500 ppm so as to avoid priming troubles, and in water with a high ratio of sodium to calcium, caustic embrittlement is caused by soda bicarbonate breaking up by heating into caustic soda and carbon dioxide. The American Society of Mechanical Engineers has placed the ratio of sulfate, computed as sodium sulfate, to alkalinity, as sodium carbonate, as one, for pressures up to 150 lb per sq in.; two, for pressures up to 250 lb per sq in.; and three for pressures greater than 250 lb per sq in. (34).

Unusual circumstances generally dictate whether or not reclaimed sewage water should be used for boiler feed. Perhaps the most notable example of such use in the United States is at the Grand Canyon of the Colorado in Arizona (35), where reclaimed sewage water is used for this purpose in the Santa Fe (N. Mex.) machine shops, and otherwise. In this instance, reclaimed sewage water is substituted for fresh water which would have to be pumped vertically 4,000 ft from springs near the floor of the Grand Canyon to the Canyon rim where the shops are situated, or transported from Flagstaff, Ariz., to the Grand Canyon in tank cars. The process of reclamation employed is activated sludge treatment in a plant which is of ample proportions and from which an effluent of sparkling clarity, low B.O.D., and suspended solids, is produced at a relatively high operation cost. However, it is much less than the cost of water from the low-level springs or from Flagstaff. The sewage treatment plant is not operated as a commercial venture, but by the park authorities on behalf of the Santa Fe Northwestern Railway Company. In addition to this industrial purpose, the water is used to sprinkle lawns and for the flushing of toilets. Naturally, a dual system of water piping is employed.

It is not unusual to find sewage water being used for cooling purposes. For many years the circulating water coils from an internal combustion gas engine operated at the Joint Disposal Plant of the Los Angeles County Sanitation Districts (California) were immersed in the effluent wet well of an activated sludge plant, and operated with perfect satisfaction. A recent example (36) is the contract for purchase of 40 mgd of sewage effluent from the Baltimore, Md., sewage disposal plant by the Bethlehem Steel Company plant at Sparrows Point, Md., at about $1.64 per million gal. The effluent is that from the city's activated sludge process. It would otherwise be wasted to the river. Obviously, as a commercial venture in industrial water reclamation it would be a financial failure.

No small amount of difficulty is involved in algal and slime growths in cooling and condensing water. The use of disinfectants, such as chlorine, in circulating systems, is quite common and current, and it appears obvious that where reclaimed sewage water is to be used in such a manner these difficulties will be multiplied because of the chemical consistence of sewage water. According to William O'Connell (letter to Committee) this factor should be taken into account in evaluating the comparative merits of reclaimed sewage water and other waters for this purpose.

The Committee concludes that the use of reclaimed sewage water for boiler feed purposes is perfectly logical where such water is better than any other adequate supply available in the area, or is less expensive than a supply of equal character, and that the salvage of water for this purpose is not to be excluded on any grounds that it implies in nuisance or menace to health, but rather that it must depend for its success upon comparative features in the area and industry in which it is to be applied. It is significant that the use of sewage water in industry is so rare as to command notice in the editorial column of national engineering journals when it occurs.

THE RECLAMATION AND USE OF FERTILIZER FROM SEWAGE

The production of sludge at a sewage treatment plant is unavoidable. The most economical and acceptable manner of disposal determines the type and degree of conditioning available. If the disposal includes its distribution or sale as fertilizer, such procedure will probably be invoked.

Barring health hazards, the acceptability of sewage fertilizer produced in a given area:

(*a*) May be evaluated by comparison with the type and characteristics of commercial fertilizers prepared for soils and crops within the economical distribution distance from the plant where the sewage fertilizer is produced;

(*b*) Its value may be reckoned in terms of fertilizer filler—a material which is utilized in the preparation of commercial fertilizers in much the same manner as peat, tankage, and other organic materials low in plant essentials bolstered up by the addition of the elemental plant requirements, and

(*c*) It has been said to contain "plus" values (37) which are not readily susceptible to measurement by laboratory yardsticks, the determination of which depends upon observation of influence upon plant culture following application of the sludge.

Elements Essential to Plant Growth.—The elements essential for plant growth which may be added in the form of plant fertilizer are nitrogen, phosphorus, and potassium. These three are drawn upon so heavily that soil which is being constantly cropped is depleted quite rapidly in the absence of careful soil culture and conditioning. The elements hydrogen, oxygen, and carbon, essential to all plant growth, are secured from air and water, are not subject to depletion, and need not be added to the soil in fertilizer form. There are, in addition, many elements needed in small amounts for a wide variety of plants and crops (38), and which are usually found in sufficient quantity in the average soil, although at times they may be added either with the fertilizer or otherwise. They include tin, calcium, magnesium, sulfur, iron, manganese, zinc, boron, aluminum, arsenic, cobalt, chromium, radium, uranium, silicon, strontium, and lead.

Nitrogen is required by all plants—particularly those in which extensive leaf development is required (17*a*) (39). It is thus of particular value in fertilizing grass, lettuce, spinach, celery and the like, because it stimulates the growth of leaf and stem. Phosphorus is essential for some phases of plant growth. It accelerates ripening, develops root growth, and is said to increase resistance to disease. Potassium is an important factor in vigorous growth. It increases resistance to disease but delays ripening and is needed in the formation of chlorophyl.

Almost without exception the commercial fertilizer applied to the soil is blended to provide the essential elements—nitrogen, phosphorus and potassium—in a ratio which will provide maximum benefit to the soil and the crop to be grown. The variables in this ratio are endless. They are designated to indicate numerically the percentages of nitrogen, phosphorus, and potassium, in that order:

> "No general rule can be given for fertilizing soils since conditions are so variable and soils differ so widely in their characteristics. The only sure way of determining the fertilizer needs of crops of any particular soil is by actual field tests" (40).

Untreated Sewage Solids.—It has long been recognized by American health authorities (17*b*) and others engaged in the practice of sewage treatment and disposal, that fresh domestic sewage sludge is, to all intents and purposes, substantially the same as night-soil and, as such, is unfit for use in fertilizing soils which may, shortly thereafter, be cropped with foodstuffs, particularly those which are to be eaten raw. Untreated domestic sewage solids have at times been disposed of by broad irrigation in the culture of crops used for pasturing beef cattle, sheep, horses, and the like, as well as for raising harvested forage crops. There are, however, some classic examples of the transmission of tapeworm through its life cycle by this means, although such transmission may be thwarted if the meat is fully cooked (13) (18).

It is the universal rule that raw sewage shall not be used in the production of foodstuffs to be consumed by humans in the United States although it cannot be said that the rule is always observed (19*a*). Health authorities in the United States are also quite universally opposed to the use of sewage products in any form being applied to vegetables and fruits which grow in or close to the ground and are to be eaten uncooked.

The longevity of pathogenic bacteria in an environment created by the spread or distribution of raw sewage or its wet, untreated solids content, upon a field or ploughed into the soil, is material (12). Bacterial life will persist for long periods of time therein, and consequently will constitute a potential menace to the health of those who will later come in contact with the soil or consume foodstuff raised thereon. Although a careful review of the literature fails to disclose many instances in America in which illness may be traced directly to contact with raw sewage solids under these conditions, it must be remembered that the use of such solids in crop culture is greatly restricted by prohibition and is practiced only infrequently, generally through ignorance of the law or in violation of the current concepts of health and decency, both factors which will limit the occasions where such contact is possible. It is, therefore, improbable that there are, or will be, many instances in which direct contact with raw sewage may account for illness in endemic or epidemic form. It is probably safe to predict that even in the absence of restrictive health laws, the use of raw sewage solids for crop culture or the fertilizing of fields, which are later to be cultivated and used for raising garden truck and the like, will be quite universally avoided because of public health knowledge and the violation of the esthetic standards which are incidental to present public sanitation concepts in a nation where the pressure of hunger is not greatly felt.

It is unfortunately true, however, that where the presence of famine, starvation, or hunger is experienced, as has long been the case in certain parts of the Orient and is now the case in some European countries, prohibition to the practice of irrigating table foods with raw sewage breaks down, and in an effort to conserve to the utmost the resources of these lands, urban sewage is applied to suburban farms in an effort to make the greatest use of its fertilizer value in the production of foodstuffs (30).

In 1936 the trend in sewage utilization in Germany as a land conditioner and crop fertilizer was described as follows (16*c*):

> "In Germany, sewage farms have always been popular. Now, mainly due to the present economic situation, there use is being extended at a number of places, notably, at Berlin and Leipzig. It is a significant fact, however, that some years ago before the economic position became so acute, plans were prepared for the replacement of the Berlin sewage farms

> by seven modern sewage treatment works, two of which were built. A similar situation existed at Leipzig. Summing up the situation, it appears fair to state that irrigation, as a means of treating raw or settled sewage, is largely being superseded by more modern methods of sewage treatment."

In 1938, the situation in Germany, France, Spain, and Italy was expressed in the following language (30):

> "In contrast to this report [that from the United States] the reports from the European countries, France, Spain, Italy and Germany, show a more positive attitude towards the agricultural utilization of sewage. The reason should be sought in the fact that in the highly populated European countries the increase of agricultural production has quite a different significance than in the United States, but also here, it can be observed that the experience of numerous irrigation fields in the European countries does not confirm the hygienic misgivings felt in the United States.
>
> "A review of the reports of the European countries shows that intensive study of the question of modern agricultural utilization of sewage is at present practically confined to Germany" (30*a*).

In France,

> "He sees economic possibilities of such utilization in the cultivation of vegetables, but he also draws attention to the frequent refusals of the public to buy vegetables grown on sewage land" (30*b*).
>
> "In Spain the conditions for practical utilization of sewage are especially favorable * * *. It cannot be justifiable to destroy the values of sewage which are given in the form of plant nutrients * * * by treatment in clarifying plants * * *. The aim is * * * in Spain to carry out comprehensively the agricultural utilization of sewage" (30*c*).
>
> "In Italy, the increase of agricultural production is a vital problem, and that in the Italian policy of self-sufficiency the agricultural utilization of sewage must also be considered * * *. The complete elimination of all kinds of hygienic objections to this system of sewage utilization has been established by long time observations" (30*d*).

In Germany,

> "It is intended to develop this modern system of utilization of sewage as fully as possible * * * to achieve a partial reenrichment of underground water supplies * * * to insure and increase agricultural production in Germany * * *. Whereas [heretofore] we find municipal plants for the disposal of sewage, we now find that sewage disposal is regarded as a matter of soil improvement with the principle that irrigation must be adapted to farming requirements and not vice versa * * *. Vegetables are excluded to the greatest possible extent in the utilization of the irrigated areas. The Reich authorities * * * recognize the importance of agricultural sewage utilization for the security and increase of farm production and have therefore promoted such measures on the greatest scale. It has been decreed that sewage clarification plants may only be established where the utilization of sewage is impossible. The systems practiced are on grasslands with favorable topographic conditions, trickling irrigation, otherwise here, as elsewhere, artificial raining. On arable land the principle is always artificial raining of sewage with semi-stationary equipment * * *. It can already be recognized that modern sewage utilization is an excellent means of production, suited to ensure and increase agricultural production * * *. There has been no evidence whatever that sewage utilization has any detrimental effect for the public."

There has been no public nuisance.

> "The reason for this fact is the use of fresh sewage, the avoidance of processes of decomposition and the activity of micro-organisms on the irrigated areas which instantaneously split the low quantities of organic matter that are discharged at a time * * *. With regard to the economic aspects of such systems, the investment and operation expenses of another otherwise necessary effective clarification of sewage must be deducted" (30*a*).

No information regarding the further advances of sewage utilization in the European countries is available.

From the foregoing comments, it appears that the estimate of danger in the use of untreated sewage solids as fertilizer in European countries is modified by the country's needs; and where the pressure of economic necessity is being felt as strongly as today, authorities are willing to chance the danger of contamination in the interest of more food production. This economic pressure combined with the public health hazards inherent in the use of raw sewage solids tends to modify food habits and to eliminate the consumption of uncooked vegetables. It appears that under carefully controlled conditions fresh sewage solids may be utilized as fertilizer without great menace to public health particularly in a country where economic conditions have probably greatly restricted the use of green vegetables in an effort to produce the more stable nutritious cooked varieties needed in its present national economy; and although it is altogether likely that such use will be barred as a potential menace in a country where the pressure for food products is no greater than in the United States at this time, the situation as it exists elsewhere, and probably will continue to exist for some time, insists upon the admission that the use of raw sewage solids for fertilizer may not be ruled out solely because of the health implications involved, particularly in the culture of cooked foodstuffs.

Limiting Considerations.—Since it is decidedly unlikely that untreated night-soil or settled solids from domestic sewage will be utilized in the United States as table-food fertilizer, and because the health restrictions upon use of air-dried digested, or heat-dried activated, sludge, as well as heat-dried or composted screenings, are not unfavorable, admitting these products to the channels of commercial fertilizer trade and lending them a definite value (17*a*), further discussion relating to the use of sewage solids for fertilizer will be limited to the processed varieties.

Activated sludge which has been dried at high temperature is said to be free from bacteria inimical to human life. Thorough digestion of sewage solids coupled with air-drying is generally deemed sufficient to destroy all pathogenic bacteria contained in the sludge mass (17*c*) (20) (41) although some evidence points to the contrary, and it probably follows that sewage screenings—heat-dried or composted—are fit for use as fertilizer or filler for substantially any type of crop culture.

The quantity of solids obtained from sewage by plain subsidence will vary from 0.1 to 0.3 lb per capita per day. A survey in 1924 indicated that throughout the United States there was an average solids contribution to the sewers of 0.24 lb per C.D. (2). In untreated sewage solids, the product of subsidence of sewage from a separate system, the average of 0.24 lb per C.D. will contain approximately 3% nitrogen (39) (17*a*) (16*a*) (3*b*) (42); 2.5% P_2O_5; and 0.7 K_2O and 70% organic material. It will be removed from the tanks at about 95% moisture content. The actual quantity per million gallons will vary between quite wide limits but may be expected to average about one ton.

From sewage treated by the activated sludge process the sludge will contain the following approximate quantities of fertilizer essentials (39) (17*a*) (16*a*) (3*b*): 5% nitrogen; 3.5% P_2O_5; and 0.7 K_2O. This material will be removed from tanks at 96% to 98% moisture content. When the solids, which are the product of plain subsidence—termed primary solids—or those from secondary treatment, usually activated sludge, or a mixture of the two, are digested, the nitrogen loss is approximately equal to the loss in organic material (3*b*). Thus, if digestion is considered complete at a 50% reduction in organic solids, the digested sludge may be expected to contain from 1.5% to 3% nitrogen; 1½% P_2O_5 and little, if any, K_2O (16*b*). Heat-dried undigested activated sludge will retain substantially all its fertilizing constituents, little, if any, of which will be lost in the process of drying.

At the New York (N. Y.) Jamaica plant it is reported that screenings are centrifuged to 70% moisture, mixed with 2% chopped straw and 2% gypsum, and spread in beds 18 in. deep where they compost for 30 days (42). The resulting mass is inodorous, contains approximately 2.6% nitrogen and 1.21% P_2O_5. Its ash content is said to be less than 20%.

Fine screenings at the Hyperion Plant of Los Angeles are heat-dried to zero moisture and sold as fertilizer (43). On a dry-weight basis they are reported to contain from 1.5% to 2% nitrogen.

PROPORTION OF ANNUAL NATIONAL REQUIREMENTS

Fertilizer.—The total suspended matter currently received annually at sewage works in the United States is about one and three-quarter million tons of dry solids (estimated from U. S. P. H. records of per capita discharge and the present population tributary to plants). Under ordinary conditions this might be deemed to produce about 575,000 tons of dried digested solids, which, at 2% nitrogen, would yield 11,500 tons per year of the latter. Were all of the sewage treated by the activated sludge process and the resulting sludge dried without digestion, it would yield some 87,500 tons of nitrogen annually. Actually, the total annual production of dried activated sludge in the United States is less than 100,000 tons (17) (44) (45) (46). This is equal to 6,000 tons of nitrogen, which is about 2% of the total annual amount of nitrogen currently sold in mixed commercial fertilizers.

Filler.—The current annual consumption of mixed fertilizers of all kinds is nearly 9,000,000 tons—about two thirds of which is in the form of commercial mixtures (39). Of this, nearly 15% or 900,000 tons, is said to be filler; an amount which is more than twice the annual national production of dried sewage sludge of all kinds.

From the foregoing quantitative analyses, it may be assumed that the production of sewage sludge fertilizer need not be restricted because of present overproduction of either fertilizer or fillers. Current production at sewage treatment works is but a small fraction of requirements; even potential production does not present a very impressive figure.

The "plus" values contained in sewage sludges which do not appear to be readily measurable in the laboratory have been described in the following manner (37):

> "The fertility values together with the fertilizer values in sewage sludges may be summarized in general as follows: In addition to relatively small amounts of the principal fertilizer ingredients, sewage sludge contains 'minor' chemical elements and growth-promoting substances essential and necessary for proper plant growth. It prevents depletion of humus and is capable of increasing the fertility of the soil. It improves soil structure in general and increases the water holding capacity of sandy soil in particular. The value of sludge is not the same for all soils; neither is it the same for all crops. Except for their growth observations there is no adequate measuring stick for revealing the over-all values of sewage sludges as soil improvers and growth promoters—in short, their fertility values as contrasted to their limited worth as fertilizers based on the chemist's analysis alone."

Those who use sewage sludges extensively for fertilizing certain types of crops insist that the results obtained cannot be attributable entirely to the proportions of nitrogen, phosphorus, and potash contained therein (37*a*) (37*b*). Sludge, particularly digested sludge, promotes the growth of ground worms; and greatly increases friability of heavy soils and the water holding qualities of sandy soils. The introduction of large numbers of bacteria and Protozoa results in an increased rate of decomposition. Microorganisms such as molds, etc., appear to make inorganic fertilizers more readily available, and the almost total absence of weed seed conserves the fertilizer for the use intended. It appears that sludge does have values greater than laboratory analyses will indicate—they are tangible and real and have a marked effect upon the sale price of the material where the beneficial "plus" values have been demonstrated. It is otherwise impossible to account for the difference between the selling price of sludge and barnyard manure as citrus tree fertilizers—the former commanding about three times the price of the latter per unit of nitrogen. The extra values are not always evident; they appear in certain soils and crops. In their absence the fertilizer value must be determined solely upon analysis and in this case the digested products suffer greatly by comparison with most of the commercial brands.

Relation between Sludge Disposal and Fertilizer Production

Following the separation of sludge from sewage, there appears to be but one acceptable method of final disposal which is not a step toward the production of sewage fertilizer if the latter is desired—namely, barging to sea, as exemplified by operations at the Wards Island Treatment Plant, New York City, the Joint Meeting of Municipalities in Essex and Union Counties, New Jersey, and elsewhere. Any other method currently practiced involves one or more moves in the direction of fertilizer production—not particularly with that objective in mind, but because they are inherent in sludge disposal processes.

Manufacture and sale of heat-dried activated sludge fertilizer involves:

(*a*) Separation of sludge from water by subsidence (a necessary corollary of any type of sludge disposal);
(*b*) Conditioning sludge with chemicals;
(*c*) Filtration;
(*d*) Heat drying; and
(*e*) Grinding, sacking, warehousing, sales, and distribution.

The cost of barging activated sludge from the Wards Island plant to sea approximates $4.00 per ton of dry solids (47), and this cost is significant because it probably represents, in whole or in part, the anticipated loss per ton in the production of fertilizer at the sewage treatment plant. Doubtless all methods of sludge disposal, including the manufacture of fertilizer, were investigated by the New York Authority as a preliminary to the adoption of the method now employed. At least one is justified in this conclusion. In view of this circumstance, the $4.00 figure becomes important. At Pasadena, Calif., there is no opportunity to dispose of activated sludge from the Tri-Cities Disposal Plant by barging to sea, but the cities which are parties to this sewage disposal works have recently signified their desire to dispose of wet activated sludge from the Tri-Cities Disposal Plant through lines of another authority to which the wet sludge may be rendered tributary at small cost, and have expressed willingness to pay approximately $5.00 per ton of dried solids for such disposal. This verification of the New York experience helps to establish the economics of this operation if the wet activated sludge can be disposed of without further processing than that indicated by Item (*a*) in the foregoing tabulation—namely, the separation of sludge from water by subsidence.

Experience in Pasadena is of value in determining other factors. At that plant, nearly two decades of experience in fertilizer manufacture indicates that the cost of chemicals and filtration is about one half of the total cost of manufacturing the fertilizer, so that if it is not intended to digest the activated sludge and other sewage solids but to dispose of them by a process of partial dehydration (Items (*b*) and (*c*)) of the undigested solids followed by some method leading to their final disposal, that portion of the cost of manufacture (Items (*b*) and (*c*)) of fertilizer may be deducted and the remaining processes of drying, grinding, sacking, warehousing, and selling will usually cost less than the revenues derived from the sale of the resulting sludge as fertilizer. In fact, based upon such a method of computation, the fertilizer plant may show a considerable profit.

In correspondence with the committee during 1941, Longdon Pearse called attention to the fact that the Chicago Sanitary District installed equipment at its West Side Plant for the incineration of activated sewage sludge. As a preliminary to burning, the sludge is conditioned and vacuum filtered. This comprises operations (*a*), (*b*), and (*c*) of the foregoing tabulation. By operating the incineration equipment to de-water the sludge, the City is producing a ton of dried activated sludge fertilizer by the use of 0.6 ton of coal. Substantially the only change in the originally adopted process for sludge disposal in this instance is the substitution of drying for incineration—using the same equipment. The features of distribution and selling are added, but the revenues which accrue from the sale of fertilizer effect an economy to the Sanitary District. The case for Chicago is influenced by the fact that steps (*a*), (*b*), and (*c*) and, in part (*d*), were deemed essential in sludge disposal and less expensive or troublesome than other methods. To show a return the fertilizer must only sell for more than Item (*e*) plus 0.6 ton of coal.

It has been proved many times that activated sludge fertilizer is not worth its cost of production if each of the items included ((*a*) to (*c*)) are charged to it. Only when certain of the steps necessary in its making are incidental to the selected method of disposal can it be made to show other than a loss.

Discounting the "plus" values in sewage fertilizers, they may usually be counted upon to command a selling price commensurate with their beneficial organic and mineral content and as a rule dried activated sludge is worth two or three times its digested counterpart. Value at the point of use must not be confused with value at the plant site. The fact that from two to three tons of digested sludge must be transported from plant to point of use to obtain the plant food value of one ton of digested sludge is a potent factor and greatly reduces the radius of the use area of digested sludge except as a filler.

Manufacture and sale of dried digested sludge fertilizer involves:

(*a*) Separation of sludge from water by subsidence (a necessary corollary of any type of sludge disposal);

(*b*) Digestion;

(*c*) Transfer to air drying beds; or (alternate) conditioning and filtration, with possible composting or drying;

(*d*) Removal from the beds, maceration, storage, sales, and distribution; or (alternate) direct application to lawns, parks, orchards or crop lands; including sales and distribution.

Each of these items is involved in the disposal process indicated by sludge digestion; therefore the preparation of the resulting dried mass as a low-grade fertilizer or filler is a comparatively simple, inexpensive procedure. (In some instances where the dried sewage sludge fertilizer has an especially good reputation, the dried residue from the beds is ground, sacked, and sold as a finely divided organic fertilizer.)

An impressive number of sewage disposal plants in the United States and Great Britain dispose of digested sludge to those who use it as a fertilizer and soil conditioner (16*d*). Classifying typical procedure, one finds that:

(*a*) The greatest number give the sludge to those who are energetic enough to haul it away, in most instances removing it from the beds at public cost, thus realizing the cost of hauling from the site as the sole return;

(*b*) At a second general group of plants, favorably situated with respect to soil and crops which respond to digested sludge fertilizer, sludge removed from the drying beds is sold for prices ranging from 50¢ to $2.00 per dry ton at the plant site, transported and applied to the soil by the purchaser; and

(*c*) A few plants go to considerable lengths to prepare the sludge in attractive form and packages. This apparently yields dividends—especially in the smaller plants where prices for the prepared product range from $3.00 to $10.00 per ton, although it is not always clear whether the selling price includes transportation to place of use.

In class (*b*) (where the larger plants successfully disposing of digested sludge as a fertilizer generally fall), it is probable that the revenues defray from 20% to 50% of the sludge digestion costs. Small plants operating in the manner described in class (*c*) have at times paid the entire cost of sludge disposal and it has been stated by experienced operators of such works that no large-sized sludge digestion plant should be without the necessary equipment and facilities to convert dried digested sludge into well-prepared fertilizer attractively packaged.

Many cities and other authorities use the entire sludge production from plants under their jurisdiction on parks and other public grounds (48). A notable example of this is Golden Gate Park in San Francisco, Calif., where the entire output of the Golden Gate activated sludge and the Richmond-Sunset sedimentation plants is used exclusively in the park area.

The financial outcome of a venture into the manufacture and sale of sewage sludge fertilizer is a function of so many variables that the decision must be made for each plant individually, or at least for each general area. Choice may rest with:

(*a*) The most acceptable means for disposal;
(*b*) The size of the plant, type of treatment, and daily quantity of sludge;
(*c*) Soil analysis within a reasonable transporting distance;
(*d*) Crops grown within a reasonable transporting distance; as well as numerous others not so general in application.

Certainly one of the strongest deterents to such manufacture and sale is the inherent lack of economy in the operation unless many or all of the steps involved in production are included in the otherwise selected process of sludge disposal and charged to plant operations and not to fertilizer production.

Except where sludge can be disposed of without any further processing than concentration, the most potent reason for its use is the fact that it exists in abundance and must be disposed of, and that any return in labor or money which will offset a portion of the cost of disposal is profitable to the producing plant. Therefore, its continued use will be urged. It is a product of necessity and its use makes a virtue thereof.

During the process of biological digestion of sludge the nitrogen which the sludge loses goes entirely to form ammonium bicarbonate in the sludge liquor (3). For instance, if an untreated sludge containing 5% of solids is digested to approximately 50% reduction in organic content, the sludge liquor should contain about 1,000 ppm of ammonium nitrogen, and the quantity of such liquor that can be decanted from the sludge will be at least half of the original volume of the sludge. If the solids removal from the sewage approximates 250 ppm, the fresh sludge liquor will amount to 3,000 gal, more or less, from 1 million gal of sewage and this will contain 25 lb of ammonium nitrogen or 30 lb of ammonia.

There is no known plant at which nitrogen is recovered from sludge liquor; nevertheless, the fact that it exists in abundance therein leads to the following discussion of four general methods which suggest themselves for its recovery (49):

A calculation based upon average values indicates that a well-designed still with suitable heat exchanges could recover the ammonia, utilizing less than one fourth of the sludge gas produced in digestion as fuel, since it would be necessary to vaporize only a small part of the liquor. In addition, about 3.85 parts of Ca O will be required to recover one part of ammonia. The value of ammonium nitrogen weighed against the capital cost involved in the construction of the still, its operation, cost of the lime, and the value of the sludge gas, will decide whether or not such a method of recovery can be made profitable. The picture is not very promising. Its best chance of success will exist in a plant which uses lime to aid in the filtration of digested sludge where the lime constitutes a necessary expense to filtration and is not a charge against ammonium nitrogen production. The second method is to mix the sludge liquor with sulfuric acid and crystallize ammonium sulfate by solar evaporation. Approximately one ton of sulfuric acid is required to produce one ton of ammonium sulfate, the latter having a value somewhat less than twice the former. The economy of this operation will depend upon annual evaporation statistics, cost of, evaporation beds, and capacity to operate without odor nuisance. It will probably have its best chance of success in the arid West or Southwest.

A third procedure might be the use of zeolite. The Guggenheim process for sewage treatment proposes recovery of ammonia from sewage by this method. The net result of the use of zeolite is to concentrate the ammonia from its dilute solution into a fairly concentrated solution of ammonium chloride, mixed with sodium and calcium chlorides. It is then necessary to add lime and distill off the ammonia; but the lime requirement in this instance is less than one half that for direct distillation. It appears doubtful that the advantages of concentrating the ammonia are sufficient to justify the expense of zeolite treatment.

A fourth possibility is by precipitating magnesium ammonium phosphate. For this purpose salt works bitterns may be used to furnish the magnesium and mono-calcium phosphate. The resulting product would be a white granular material which would not cake or deteriorate in storage. It would furnish both ammonia and phosphate in a form readily available for plants, and yet its solubility is low enough so that it is not readily washed out of the soil. Production would be expensive, but the somewhat unique value of the product is such that investigation may eventually prove this process to be of some value where the necessary constituents are available at moderate cost.

Gas Reclamation and Utilization

A valuable end product produced in the anaerobic digestion of sewage solids is sludge gas. Typical analysis of this gas indicates that it has the following chemical properties:

Methane (CH_4)	55 to 75%	(Average 65%)
Carbon dioxide (CO_2)	25 to 40%	(Average 35%)
Nitrogen	Zero to 3%	
Hydrogen sulfide (H_2S)	Trace to 3%	
Illuminants	Trace	

There is doubt about the presence of nitrogen in undiluted sludge gas (3), it being argued that any nitrogen released in the decomposition process will go into solution in the supernatant liquor. This consideration is not of especial importance, however, as the principal constituents with which one is concerned when determining the value of the sludge gas, as indicated by its ability to produce heat and do work, is methane; the principal dilutent carbon dioxide being an inert gas, the presence of which merely reduces the calorific value per unit of total volume of gas. The presence of excessive quantities of H_2S may render the gas so corrosive as to indicate treatment for the removal thereof (16*e*), slightly increasing the cost of production (see Manufacturers Specifications).

In anaerobic sewage sludge digestion some of the volatile substances are rapidly decomposed. Among these are the fatty substances, greases, fats, and soaps (50) (51). These substances in turn furnish the best quality of gas (62% to 75% CH_4). Proteins decompose into a similar grade of gas but in lesser amounts per pound digested. Comparatively small amounts of cellulose and cellulosic material digest in the usual period allowed for sludge digestion at a sewage treatment works; although the methane content of the resulting gas is considerably lower (averaging 45% to 50%).

The weight of the gas produced in each instance is greater than the weight of the material decomposed (51), the increase corresponding to the quantity of water which has entered into the reaction. The weight of the gas produced is approximately 1.2 times the weight of organic material digested. The weight of a standard cubic foot of gas of 65% CH_4 will average 0.064 lb.; thus per pound of organic material consumed in the digestion tanks, approximately 18.5 cu ft of gas, with an approximate calorific value of 650 Btu per cubic foot, is available. Specific analysis of the solids to be digested will, of course, modify this generalization.

Under controlled digestion, the average rate of gas production at a sewage treatment works will approximate 1 cu ft per capita per day which, equated to horsepower, indicates that about 1 hp-hr may be reckoned for each 17 persons tributary to the sewage treatment works. Thus a city of 50,000 population will have a potential sludge gas power generating capacity of 2,900 hp-hr per day.

Regarding sulfides, it is suggested by manufacturers of internal combustion gas engines that any sulfides in the gas are harmful, but that within reasonable limits their effects can be controlled by care in operation. If the gas that is to be used contains 2% sulfides by weight, it is frequently specified that the owner of the gas engine must provide for the maintenance and replacement of parts which are subject to corrosive attack (16*b*). Cast iron is not readily susceptible to corrosion and generally 0.25% of sulfides will not seriously affect steel and copper elements in the engine, although care must be taken to scavenge the engine with air as soon as it is shut down. Conversely, if the vapors that remain in the engine when it is shut off are allowed to cool and the acid condensate is allowed to precipitate in the cylinder walls and elsewhere, even 0.25% of sulfides will destroy or seriously impair the valve and exhaust assemblies, and to some extent the cylinder walls and rings; 0.1% of sulfides does not appear to have a harmful effect upon the engine if the lubricating oil is kept reasonably fresh.

Within the past few years engine manufacturers have developed what is known as the vapor phase system of cooling engines. In this system the circulating water ranges from 210° to 220° F constantly and enough of it is circulated so that the temperature rise through the jackets is only 5° to 6° F. The water coming from the engine is led to a flash tank where pressure is released to the atmosphere, resulting in the formation of some steam which later is condensed in a radiator cooler and pumped back into the main stream of water. The main stream does not undergo any cooling process before it is returned to the engine; thus the engine operates constantly at a high temperature. This type of cooling greatly decreases the corrosion ordinarily caused by sulfur and organic acids formed through the combustion of the fuel. It permits the use of gas with a higher sulfur content than it has heretofore been possible to use.

Sludge gas for power generation was first utilized in the United States at the sewage treatment plant at Charlotte, N. C., in 1928 (52). This, in turn, was the first American counterpart of the original sewage gas engine installed at a leper colony in Bombay, India, in 1907. In the early 20's a number of plants were installed in England and Germany and, in the United States, since 1928, the practice of utilizing sludge gas had progressed to the place where an incomplete tabulation prepared in 1941 indicates (53) that 115 sewage treatment plants, 180 sludge gas engines operate 79 generators, 49 blowers, and 40 pumps. The engines range in size from 3 to 1,440 hp, with most of them less than 500-hp capacity.

The impressive numbers of installations noted in the 1941 tabulation indicate that sludge gas is an acceptable fuel for internal combustion gas engines. Its value may be reckoned in terms of substitute fuel or other source of power; the value of the destroyed organic sewage solids as fertilizer and the cost to produce and capture the gas.

Dried activated sewage sludge fertilizer has usually been found to cost more to prepare and market than is returned from its sale provided the complete processing is included in its cost of preparation (53*b*). The over-all loss to the treatment plant in the production and disposal of 1 ton approximates $4.00. To determine the value of sludge gas in terms of undigested sewage solids utilized as fertilizer, it is necessary to determine the net cost of digestion, sludge disposal, and gas collection. The following approximation is made in terms of 1941 costs.

The cost to digest, dry, and collect the gas from 1 ton of sewage solids may be summarized about as shown in Table 1. This analysis assumes a 50% reduction in volatile solids in a raw sludge mass averaging 70% volatile solids originally. It further assumes that the 50% reduction in volatile solids, amounting to 700 lb per ton, will produce about 12,000 cu ft of gas (a little less than 18 cu ft per lb of volatile solids destroyed) having a calorific value of 650 Btu per cu ft.

Between the limits of a profit of $3.10 per ton of raw solids removed from the sewage and the loss of $3.43 are almost as many different possibilities as there are sewage treatment plants, and there are, of course, plants where unusual conditions will result in a profit or loss lying without the extremes noted. Most, however, will fall within. Actually, circumstances seldom combine to show returns fully equal to costs; nor is such a demonstration necessary to indicate that the values remaining in the sludge residue or derived from the process of digestion are equal to or greater than those inherent in dried activated sludge or other undigested sewage solids—fertilizer. Therefore, it may be stated that the destruction of volatile sewage solids by digestion will yield a gas, the value of which universally exceeds the value of the solids themselves as a processed fertilizer.

TABLE 1.—COST OF DIGESTING, DRYING, AND COLLECTING GAS FROM ONE TON OF SEWAGE SOLIDS

No.	Description	COST, IN DOLLARS PER TON[a]	
		From:	To:
1	Controlled separate sludge digestion	1.75	
	Air Drying		
2	On underdrained beds	1.60	
3	In shallow lagoons	0.15	
4	On drying beds ready for final disposal	1.80	3.35
5	Selling price of dried digested sludge	−0.65[b]	+1.30[c]
6	Net cost, removed from drying beds	0.50	4.00
7	12,000 cu ft of gas at 4.75¢ to 30¢ per thousand[d]	0.57	3.60
8	Sludge digestion, including recovery of all gas values	−3.10	+3.43

[a] Entire cost, in dollars per ton of (dry) raw solids.
[b] Equivalent of $1.00 cost per ton of dried digested sludge for removing from beds.
[c] Equivalent of $2.00 revenue per ton of dried digested sludge on drying bed.
[d] Equivalent of 8¢ to 50¢ per 1,000 cu ft for 1,100 Btu of gas.

It has been demonstrated repeatedly that the cost of generating electrical energy using a sludge gas engine as the prime mover costs about 0.6¢ per kw-hr unless conditions differ materially from those commonly encountered (54). Costs have been variously reported at from 0.4¢ to 1.0¢ per kw-hr. Commercial power purchased in large quantities can be bought, at times, for about 0.6¢ per kw-hr, but it is seldom possible for a plant, required to serve a city of 100,000 or 200,000 population, to buy electrical energy for such a price or less. More often the cost will approximate 1.0¢ per kw-hr unless special concessions are made by municipally owned public utilities or the like. Commercial power at 0.6¢ per kw-hr indicates that it is being purchased in relatively large quantities, and if available at that price, one must not look to power generation with sludge gas as an economy measure except under the most favorable circumstances. However, if the over-all cost of power generation with sludge gas equals, or is less than, the cost of commercial power, the value of the sludge gas may be reckoned in terms of a substitute fuel which would serve the same purpose.

Natural gas with a calorific value of about 1,100 Btu wholesales for from 8¢ per 1,000 cu ft in the South-Central oil producing states, to 50¢ in or near the New England States area. This is equivalent to from 4.75¢ to 30¢ per 1,000 cu ft for 650 Btu of gas and establishes those limits of value for sludge gas. If no natural gas is available, as is reported in some of the Northeastern areas, artificial gas of about the same heat value as sludge gas costs from $1.00 to $2.00 per 1,000 cu ft, which obviously eliminates it as a substitute fuel. In no instance is the wholesale price of natural 1,100 Btu gas reported as less than 8¢, and only under the most favorable circumstances does it sell for less than 15¢, which is the price for large blocks purchased in Southern California, typical of an area where natural gas is cheap and plentiful.

Sludge gas is frequently utilized in heating the digesting sludge mass, control of temperature being one of the important factors in accelerating sewage sludge decomposition and consequently gas production. Therefore, the gas assumes a value for this purpose. Fortunately the generation of power from an internal combustion engine may be a by-product of digestion tank heating, although the reverse view is usually assumed (55) (58) (59) (60). Of a possible capture of 80% of the energy in the gas, 26% alone goes to power, and the remaining over-all 54% may be captured from the exhaust gases and the jacket water and utilized in sludge heating; that is, "the heat balance for temperature control remains about the same whether the gas is used to produce power or burned directly under a boiler."

The economy of sludge heating for uniform temperature control is unquestioned where the plant size is sufficient to warrant continuous supervision. However, since either controlled or uncontrolled temperatures in the digesting mass eventually produce the same results, the value of temperature control is expressed only in reduced cost of sludge digestion structures and an increased and more uniform flow of gas and is not to be judged by comparison with fertilizer value of destroyed solids.

Quality of sludge gas is dependent upon quality of solids and hydrogen-ion balance in the digesting mass. Rate of production varies with the:

(1) Temperature;
(2) Quantity, character, and percentage settleable of solids;
(3) Rate of flow of sewage through the plant with all of its implications;
(4) Sludge bulking; and
(5) Filter unloading and the like, all factors which cause wide variations and render difficult the economic utilization of 100% of the gas produced.

Without supplemental fuel, or extensive gas storage facilities, or a combination of both, much of the gas produced will be wasted or at least will not be available as a uniform, continuous source of power.

Oil burning Diesel engines which will also operate on gas, render Diesel oil a substitute fuel (56). Butane, or rock gas, natural and artificial gas, as well as gasoline, may be used as substitute fuels with success and with but minor adjustments to the carburation of internal combustion gas engines (57).

In the determination of the economics of the use of sludge gas as internal combustion engine fuel each plant will present a different combination of circumstances and factors which must all be equated to determine (*a*) if all of the sludge gas is to be utilized, following which (*b*) the cost of gas storage must be equated to the cost of a substitute fuel which latter may be used to iron out deficiencies in sludge gas production. Average approximate equivalents are as follows:

1,000 cu ft of sludge gas equals:
1,000 cu ft of artificial gas;
590 cu ft of natural 1,100 Btu gas;
6.4 gal of butane;
5.2 gal of gasoline;
4.6 gal of Diesel oil.

The increasing popularity of sludge digestion with its corollary of power generation is testimony to the economy of this process of solids disposal (53). For the present at least, the by-product of the process with the most consistent value is sludge gas, with digested sludge finding increasing favor as a low-grade fertilizer or filler and as an excellent conditioner for public grounds where it is otherwise not commercially valued. Since there are no health implications involved in the use of sludge gas as fuel, it may depend for its salvage value upon comparison with the purchase price, availability, and adaptability of equivalent fuel substitutes.

Reclamation of Grease from Sewage

The term "grease" as it relates to sewage is usually descriptive of all ether or chloroform soluble materials (depending upon which is used as the solvent) contained therein and may include fats and their acids, insoluble soaps, inorganic oils and (again depending upon the solvent used), some waxes and resins (9) (61) (62). Grease is present in varying amounts in all sewage of domestic origin. It is present in organic form in industrial wastes from plants processing vegetable and animal products. Likewise, it appears in inorganic form in wastes from plants and shops manufacturing, maintaining or operating machinery, refining oils and manufacturing bituminous materials, gas, and the like.

Quantitatively and qualitatively the grease content of sewage will vary widely. In the purely domestic sewage treated at the Tri-Cities activated sludge plant in Pasadena (63) (tributary population of 140,000), grease (ethyl-ether extract) averages about 0.011 lb per capita per day, the equivalent of approximately 15 ppm in the sewage. In this sewage it is almost wholly organic, saponifiable fat, slightly mixed with oils and greases from garages, automobile washing plants, and the like. In the sewage of a municipality where there are reasonably extensive manufacturing enterprises, the grease content will vary from 15 ppm to as many as 100 ppm and the quality of the grease will be found to be influenced greatly by the character of the industrial establishments served (9). An example is cited of 489 ppm in a sewage flow of 145 mgd at Gloversville, N. Y., where industrial wastes from tanneries are present in large quantities (9). No general or average quantity may be stated, the influence of industry being proportional to the number and character of industries served and the flow therefrom relative to the domestic flow. About 15 ppm may be stated as the minimum value and from that the grease content of sewage and industrial wastes range upward through combined sewage and domestic wastes as illustrated at Gloversville, to a grease content of 2,000 ppm to 5,000 ppm for fish wastes, meat scraps rendering plants (62*a*); 150 ppm to 15,000 ppm for wool scouring, and the extraordinary 70,000 ppm for rice-bran processing plants manufacturing Vitamin "B" concentrates. There are as many variations in the quality and quantity of grease in sewage as there are combinations of sanitary sewage and industrial wastes in the sewers.

In every sewage treatment works which includes subsidence as one of its processing features, a portion of the grease in the sewage will be removed by settling or flotation and it is from these concentrates that there is afforded the possibility of grease reclamation. Methods are provided which will assist in the flotation of grease and increase the over-all removal from sewage. Current knowledge on this score has been summarized briefly as follows (9*a*): "a considerable proportion of the ether-soluble matter in sewage can be removed by sedimentation and plain skimming. Moreover, the available data show, in general, that a somewhat larger proportion can be removed if the sewage is aerated prior to sedimentation and skimming. Experiments indicate, furthermore, that aero-chlorination prior to sedimentation and skimming accomplishes a still larger removal of grease."

In 1938 a plant sale experiment (64) indicated the percentage removal of grease from the sewage without aeration or chlorination to be 38; with aeration alone, 50; and with aero-chlorination, 80. These results were achieved with 0.11 cu ft of air per gallon of sewage and 2 ppm chlorine. Data indicating the effectiveness of these methods are limited, and insufficient data are available to predict the effect of given quantities of air or air and chlorine upon sewage of known characteristics.

Grease recovery from sludge has been much discussed in sanitary engineering literature and it is rather conclusively indicated that, unless alternative sources of cheap grease are eliminated, there is little prospect of profitable grease recovery from sludge except under the most unusual conditions as, for instance, the presence of large proportions of wool scourings, packing-house wastes, or the like.

Grease recovery from sewage skimmings has better prospects. Analyses of sewage skimmings indicate 30% to 50% grease and may average 25 to 50 lb per million gallons of sewage. Grease is recovered by acidifying the skimmings, heating with steam, and pressing. The resulting product contains saponifiable matter mixed with inorganic grease from which it must be separated to be of much value. The combined product is dark in color and unsalable in a market where other greases may be cheaply procured.

The sewage works at Bradford, England, is the outstanding example of a grease reclamation plant (65) (16*f*). Industrial wool washing plants tributary to the Bradford works process one fifth of the wool of the entire world and four fifths of that grown or imported into England. Weekly the sewage works produces from 500 to 600 tons of grease from wool scourings. The Bradford works has presented the following financial statement:

> "In the year 1903 it is recorded that 166 tons of grease were recovered and the first sales realized $1,110.00 [the committee computation is based on: £1 equals $5.00]. In five years the tonnage had grown to 1,606 with

> prices ranging at about $40.00 per ton naked, and sales amounting to $57,500. In 1918 the tonnage became 4,524; with the peak price of $325.00 per ton naked, and an income from sales of $633,000.00. In 1925 the yearly tonnage had risen to 6,271, selling price about $45.00 per ton naked, the income $482,000.00 and the stock at a very low point." [For the] financial year ending March 31, 1940, grease sales will exceed $400,000.00, the month of February constituting a record with a sales value of $80,000.00, although the full effect on world trade had not been fully felt at that time. It is predicted that during the year 1941 several times the return of $400,000.00 is quite within the bounds of possibility. Twenty-thousand tons of sulfuric acid is used annually in the production of about 28,000 tons of grease."

Without the stimulus given to the sale of native grease by the current war, the works at Bradford would probably be severely pressed to show economy in grease recovery by itself. The plant report states that at the outbreak of present hostilities "tens of thousands" of tons of grease were in storage at the plant site (65). There is nothing so far in the experience at Bradford from which to conclude that grease reclamation from sewage is a profitable venture, except under the most unusual and favorable circumstances.

For each thousand pounds of grease added to digesting sludge, approximately 760 lb of grease will be destroyed in one month of controlled digestion (61), yielding about 13,250 cu ft of gas (76% CH_4). At from 4.75¢ to 30¢ per thousand this gas will have a value of $0.65 to $4.00 if it is entirely utilized in power or heat production. Grease is of doubtful value as a fertilizer. It is, in fact, considered injurious to many soils. Its value as fuel in a process incorporating incineration of sewage solids roughly approximates 30,000,000 Btu per ton. These factors may be considered in more specific form in judging the merits of an individual venture in grease reclamation from sewage. With respect to grease recovery at the Bradford works, it is stated (65):

> "The presence of the grease would greatly have enhanced the value of such gas, but such a procedure would have resulted in heavy losses to the corporation as the grease values would have been affected without any compensating advantage."

Until the industrial waste containing grease leaves the establishment and enters the sewer, mingling with the other sewage flowing therein, its reclamation is not deemed to be implied in the title of this report and therefore such wool scouring, tannery and meat-packing wastes and the like, as are treated at the source for grease recovery, are considered as outside the scope of this investigation.

The sewage treated in the Bradford works contains approximately 890 ppm of grease, 60 ppm of which are lost in the effluent (16*f*). Sludge which is finally pressed contains 40% grease; whereas the dried residue after grease has been removed contains 16%. The 40% grease content of the sludge prior to pressing compares favorably with the grease content found in settling tank scum, and were there sufficient quantity of the latter collected in the ordinary sewage treatment works; and further, were the grease almost wholly of organic origin, it is possible that the results at Bradford could be duplicated as and when desirable at other sewage treatment plants.

Unfortunately this is seldom the case. Almost without exception the quantity of grease obtained as scum is insufficient to warrant the construction of reclamation works, and its quality is so impaired by admixture of mineral oils that the cost of recovery exceeds the revenue likely to be produced, except under the most unusual circumstances.

No health hazards seem to be involved in the use of grease reclaimed from sewage (16*g*). The processes of acidification and heating, as well as those involved in the further manufacture of grease-bearing products, all contrive to render the reclaimed grease free from harmful bacteria. The reclamation of grease apparently must "rest its case" with its value as a commercial product in competition (particularly in the western hemisphere) with the many other sources of cheap grease. It is not apparent at this time that the reclamation of grease from sewage is a fruitful source of revenue or is needful in national economy.

AMERICAN SOCIETY OF CIVIL ENGINEERS
Founded November 5, 1852
TRANSACTIONS

Paper No. 2170

THE AMERICAN SOCIETY OF CIVIL ENGINEERS TODAY

ADDRESS AT THE ANNUAL CONVENTION, MINNEAPOLIS, MINNESOTA, JULY 22, 1942

By E. B. Black,[1] President, Am. Soc. C. E.

America today is joined by other nations in an effort to prevent the world-wide destruction of civilization, and our responsibility as American citizens puts us in the position where it is necessary for us to pledge and to deliver to that cause whatever we have of engineering ability, of constructive effort. Our debt to America for the privileges we enjoy as Americans, and for the preservation of those privileges for the future, is one we can never fully repay.

Such a pledge presents problems, but our engineering forebears met and solved problems of relatively equal importance and complexity. There are times when we can best fit ourselves to meet the demands of the present and of the future if we

> "Turn back the clock of time 100 years
> And for an hour or two show once again
> The hope and courage of those dauntless men
> Who laid our firm foundation."

I trust that we shall never forget that the present and the future of our country, and of the American Society of Civil Engineers, depend on what you and I do with the heritage bequeathed to us as engineers and Americans by those dauntless men who laid our firm foundation through the 320 years of our country's existence, and the 90 years of our Society's activity.

The pressure of our obligations to National Defense prevents our proceeding, at this time, along the course we normally would follow. War conditions change rapidly from day to day, and from day to day we must change our plans, and our rate of speed if necessary, to accomplish the results our country requires. Occasionally, however, we must take time out to take stock of our assets and liabilities, to plan both for the present and the future, so that at the end of this war we will be prepared to secure a just peace, a world peace planned to control war.

---

[1] Cons. Engr. (Black & Veatch), Kansas City, Mo.

You are familiar with the oft-repeated statement by Maj. Gen. Eugene Reybold, M. Am. Soc. C. E., that "This is an engineers' war,"[2] that there "can be no engineering as usual" until after this war is over. The General's statement does not mean that engineers had anything to do with starting the war, but that engineers will have to stop the war; that engineers will have to provide the ideas, develop the plans, and perform the engineering work necessary to prepare for and win the war. The problems to be met and solved are here now. Because of their number and complexity, and the number of engineers required for their solution, it is easy to see why there "can be no engineering as usual" until this war is over.

We know, of course, that engineers cannot do all of the thinking and all of the work necessary to prepare for and win the war, but, at the same time, no one familiar with the work required of engineers at this time can do other than agree that never before has the engineer played so important a part in the preparation for and the direction of the activities necessary because of the war. Today engineers are in demand; and, each day that the war continues, our responsibility increases and there are changes in the problems that we will be required to meet and solve in order to win and to secure a peace worthy of our effort.

It is my hope that, when this war is ended, this Society will be prepared to direct the continuation of constructive engineering work necessary for our country to continue as nearly as possible on a "business as usual" basis. Such a result will tax our ability to perform effectively as citizens as well as engineers. Under no circumstances can we hope for such success unless we make the necessary plans before we require action.

With few exceptions the engineering profession is made up of men who live by the sweat of their brows; men trained to plan and think along definite lines; men whose interest in, and application to, the problems of their profession prevents their spending much time in community, state, or national affairs, at least until those affairs require unscrambling; men to whom citizenship activities that require following established political practices in order to get things done mean little. The June issue of *Headlines*[3] brought to us the comment of one of our well-known columnists about the need and the lack of engineers in the governing bodies of the United States, in these words:

> "This war requires sound leaders to be familiar with science, engineering, technological planning and management.
>
> * * *
>
> "Too bad half the members of Congress aren't engineers, so we would have intellectual honesty and precision of thought."

Whether or not members of the profession need go to the extreme suggested is a problem, but there can be no doubt about our obligation to prepare now to fight effectively for a peace to control war; that should be our first postwar activity.

---

[2] "This Is an Engineers' War," by Eugene Reybold, *Civil Engineering*, June, 1942, p. 293.

[3] *Headlines* (Society House Organ devoted to the Promotion of Local Section Publicity), June 15, 1942.

Our obligation to our country and to our profession requires us to carry on without interruption the work of the Society so that we may also carry on the National Defense work required of us as a Society and as individuals.

In November, 1852, almost 90 years ago, the American Society of Civil Engineers was founded. Its record has been one of effective support of our government. As years have passed, and as new conditions have produced problems requiring changes in operation, no effort has been spared to keep the Society in pace with the constantly increasing requirements of the profession. Perhaps the most effective change has been to bring the Society to the members, through the Local Sections, and to students (those future members of the Society), through the Student Chapters.

The assets of the Society consist mainly of men who have had the vision to spread the gospel of the importance of citizenship and of sound, ethical engineering practice among its members and among those who come in contact with the profession through the usual channels of everyday life. A sound financial policy, a bank account, and the ownership of real property are also assets, and the Society has all of these things.

No professional organization can operate effectively without the unstinted effort of its governing body and its members, and without doubt the Society has long had the benefit of such effort. It is directed by an elected Board of twenty-six men (officers who devote from four to eight weeks each year to Society affairs), and by the executive organization at Society Headquarters operating full time under the direction of a full-time Secretary.

The Board of Direction plans and directs operations of the Society through eight committees of the Board—the Executive, Honorary Membership, Districts and Zones, Professional Conduct, Publications, Membership Qualifications, Division Activities, and Society Relations committees.

Seven Committees serve in an advisory capacity to the Board on the Alfred Noble Joint Prize, the Columbia University Scholarship, the Freeman Fund, the J. Waldo Smith Hydraulic Fellowship, the Retirement System, Securities, and Society Property.

Three administrative committees, each with one Director of the Society as a contact member, are in charge of Local Sections, Juniors, and Student Chapters.

Six Professional Committees, each of which also has a Director of the Society as a contact member, have in hand Engineering Education, Registration of Engineers, Fees, Salaries, Professional Objectives, and Employment Conditions.

A Committee on Technical Procedure and the National Committee on Civilian Protection in War Time complete the list of committees other than those in the Technical Divisions.

The Society supports twelve technical divisions operating under small executive committees, dividing into eleven sections all design, construction, and operating problems with which civil engineers are concerned. The twelfth, the Engineering Economics Division, combines the financial problems of the other eleven divisions and cooperates with those divisions through liaison members of those divisions.

The Society has joint representation with other national engineering societies on the administrative bodies of eleven organizations, such as United Engineering Trustees, Inc., Engineering Foundation, National Research Council, American Standards Association, and the Engineers Council for Professional Development. It also has thirty-four representatives on sectional committees of the American Standards Association and on seven technical committees on Engineering History, Lumber Standards, Concrete and Reinforced Concrete Specifications, Paving Brick, Federal Map Making Efforts, Safe Highways, and Yield Point of Structural Steel.

The Technical Division committees total more than 100 and bring the total number of operating committees of the Society to more than 125. All of the committees of the Society are necessary and of importance for the planning and guidance of Society activities. Time prevents detailing some of the interesting activities of these committees, but there are five on whose proper and continuous functioning the welfare of our Society depends, and to which our attention should be especially directed: (1) The Publications Committee, (2) Membership Qualifications, (3) Local Sections, (4) Juniors, and (5) Student Chapters.

The Publications Committee has charge of all Society publications; in the year 1941 it released a total of twenty-eight issues: *Proceedings* (10), *Civil Engineering* (12), *Transactions* (1), *Manuals* (4), and *Yearbook* (1), totaling about 493,000 separate numbers or volumes, containing 102,337,000 pages. It is through these publications that the news of the Society is made available to the membership and the record of its technical operations is made permanent.

Outside the medium of Society publications, the members of the Society are kept in contact with Society operations through the Local Sections, and the guidance of these Sections is through the Local Sections Committee, an Administrative Committee of the Board.

The sixty-four Local Sections of the Society now cover the United States, the Republic of Panama, Hawaii, and Puerto Rico, and include the 16,532 members of the Society resident in the United States, Hawaii, the Republic of Panama, and Puerto Rico.

Prior to the formation of Local Sections, groups of members of the Society used to gather from time to time to read papers and otherwise promote an understanding of engineering problems. These groups operated under such rules and regulations as seemed necessary. The forerunner of the Society Local Section in our host city of Minneapolis, Minn., was organized 59 years ago to entertain the June, 1883, meeting of the Society in Minneapolis, and to discuss the forming of a local Engineers Club.[4] Both of these objects were effectively accomplished.

---

[4]

Minneapolis, April 30th, 1883.

Dear Sir:

You are respectfully invited to meet the Engineers of this city in the Board of Trade Room, in the City Hall, on Friday, May 4th, at 7:30 p.m. to consider the question of appointing a committee to join with those of the Board of Trade and Chamber of Commerce, in making preparations for the entertainment of the American Society of Civil Engineers in June.

The subject of forming a local Engineers Club will also be discussed.

Signed, Andrew Rinker,
City Engineer.
Wm. A. Pike,
E. T. Abbott.

All local sections now operate under constitutions approved by the Board of Direction of the Society, and Society funds are allocated to each Local Section. Each Local Section constitution defines the objects of the organization as "the advancement of engineering knowledge and practice; the cultivation of friendly relations with all engineers; the maintenance of high professional standards; and co-operation with other engineering societies, with a view of promoting the general welfare of the American Society of Civil Engineers and the engineering profession."

The first Local Section to operate under a constitution approved by the Society was organized in 1905 in San Francisco, Calif., and today that section ranks fourth in size, with 841 members. Organization of Local Sections was a slow process. The second section, Colorado, was organized in 1909; the third, Georgia, in 1912; but in 1913 six sections were formed. In 1914 five more were formed, and at the end of 1919 a total of twenty-four sections had been organized, which have a present-day membership of 51.5% of the total of 16,532 members.

Twenty more sections were organized from 1920 to 1923, which have a present-day membership of 31.2% of the total membership, and the remaining twenty sections were formed, one or more each year, between 1923 and 1940, with the exception of the years 1926 and 1935, in which no sections were formed. Additional sections, or subsections may be formed for the purpose of decreasing the area covered, and to bring section meetings closer to individual groups of members. Texas is an outstanding example of successful operation of a one-state section, with a number of subsections, covering 8.8% of the area of the United States.

Without doubt the Local Sections have been giving members closer contact with the Society, and the Society first-hand contact with the members' problems. Both of these results are necessary if the Society is to continue to serve the membership as the membership has the right to expect.

The future of the engineering profession depends on the engineering students and the young engineers of today; and the future of the young engineer, and to some extent that of the engineering student, depends on guidance by the professional engineers. The Society puts the direction of Juniors and of Student Chapters each under the direction of an Administrative Committee.

The Society's work with engineers in training and the engineering student starts with centralized points of contact, such as our 121 Student Chapters, with 5,303 members, in the forty-eight states and the District of Columbia. Fourteen of these states have one chapter each; twenty-three states and the District of Columbia have two each; and the number ranges upward from three per state to the ten chapters in Pennsylvania and eleven in New York.

The first ten of these chapters were organized in 1920, and seventy-two were in operation before the end of 1926. From one to five chapters were added each year from 1926 to 1941, except in 1934 when no chapter was formed.

Each Student Chapter has a faculty adviser, a contact member, and, where possible, a junior contact member. All three of these men are members of the Society, and the contact and junior contact members are men in the active practice of the profession.

The rate at which civil engineers are graduated affects the Society's effort to serve them, to see that its facilities keep pace with the demand. Of the 126 colleges reporting to the Society for the Promotion of Engineering Education, 103 have adopted a plan to speed up engineering courses without shortening them by making the college year 48 weeks in every 12 months.

At the start of the 1941–1942 school year, in October, 1941, 149 undergraduate engineering schools in Canada and the United States reported a total of 10,838 civil engineering students matriculated. In the spring of 1941, 1,430 were granted degrees. The school year of 1940–1941 had a total enrollment of 108,091 engineers in all branches of engineering in the 129 accredited schools in the United States, and a total of 12,709 were graduated.

Student Chapters are receiving effective support from the schools in which they are located. In the first six and one-half months of this year, 797 applications were received for admission to the Society as Juniors. Not all of these applicants were graduate engineers, and 70 of the 768 applications analyzed had an average of 5.7 years professional experience. Fifty-nine of this group of 70 were engineering graduates. The remainder of the group analyzed, 698, were graduates from 111 engineering schools. Applications have been received this year from 100% of the 1942 civil engineering graduates from seven engineering schools.

Contact with a young engineer after he enters the active practice of the profession is something which can be maintained only as it has been in times past—through local and state sections of the societies and professional organizations, and through the contacts we as individuals can make with these young engineers. On February 2 of this year there were 4,858 Juniors in the Society, indicating that these new men in the profession see the advantage of such contacts. When 27% of our membership is made up of Juniors, men under 35 years of age, there should be little fear but that the Society will be kept in step with the present-day requirements of the profession.

Members should be interested in the fact that, of approximately 800 Juniors elected in 1941, 135 failed to qualify by paying the initiation fee and their first year's dues. Inquiry develops that many of them have been called to service in the Army and Navy, and the uncertainty of their future has prevented them from investing in the necessary membership fees.

Statistics for 1942 show that the membership of the Society is continuing on the upgrade. The year 1941 showed a net growth of 776 additions to the membership. On July 8, 1942, the net growth was 764 over and above the same date in 1941, and the indications are that by the end of the year our membership, which now totals 17,877, will reach a total of about 18,200. This year it appears probable that a smaller percentage of the membership will be dropped for non-payment of dues on September 1 than were dropped last year. The ratio, not the number of members involved, is about 100 this year compared with 125 in 1941.

An analysis of applications for admission to membership in the Society develops numerous interesting facts, a number of which are indicated in Table 1, which contains data from 1,241 of the applications received in the first six and one-half months of this year. These data are offered for the purpose of emphasizing the fact that one of the Society's principal obligations to the profession is to continue its active support of civil engineering students and Junior engineers, through Student Chapters, Local Sections, and personal contact.

TABLE 1.—DATA FROM APPLICATIONS FOR ADMISSION TO THE AMERICAN SOCIETY OF CIVIL ENGINEERS IN FIRST HALF OF 1942

Description	APPLICATIONS FOR:				
	Member	Transfer from Assoc. Member to Member	Assoc. Member	Transfer from Junior to Assoc. Member	Junior
Number of applications analyzed	116	76	178	103	768
Average age	45	44	36	31	23
Maximum age	73	66	66	33	32
Minimum age	34	35	27	27	20
Graduates, percent of applicants	74	80	69	93	99[a]
Average experience in years	23	23	13	11	....[b]
Average years in grade before transfer		11		11	....

[a] The calculated percent of 768 applications for Junior grade is 98.6. [b] Seventy of the 768 applicants average 27 years of age, and have had an average of 5.7 years of professional experience; 84.3% are graduate engineers; 698 of the number average 23 years of age; and all of them are engineering graduates.

It is difficult to forecast what the future has in store for us as members of the American Society of Civil Engineers and as Americans, but at this time it seems safe to state definitely that in 1942 the Society will show increases in membership and in financial stability, and that it will continue to make contributions of time and effective service to the profession and to America during this war period, when such service counts. There is a possibility that service of this sort is the reason for the Society's continued growth during the 90 years of its successful existence.

MEMOIRS OF DECEASED MEMBERS

LINCOLN BUSH, Past-President and Hon. M. Am. Soc. C. E.[1]

DIED DECEMBER 11, 1940

Lincoln Bush was born of Vermont and Ohio parentage on December 14, 1860, in a log house on a pioneer farm in Palos Township, Cook County, Illinois, some twenty miles from the young, ambitious little city of Chicago. His father's name was Lewis Bush; his mother's, Mary (Ritchey) Bush.

Because of his birth a few weeks after the momentous election of November, 1860, that stirred the United States to its very foundation, and because of his own heritage and environment, it was fitting that he should be named Abraham Lincoln Bush, and should later be influenced by the traditions of that name. Afterward he adopted the designation A. Lincoln Bush, and eventually this became simply Lincoln Bush, a name by which he was known throughout his later life. In his modest way he used to explain that he hardly felt he could live up to the grandeur of the fuller name.

Expecting to become a teacher, Lincoln Bush studied in the Cook County Normal School (the teachers' training school for the City of Chicago), receiving the degree of Master of Arts in 1881. After three years spent in teaching in the public schools, he studied four years in the University of Illinois, at Urbana. He attained high scholarship standing and was graduated in the class of 1888 with the degree of Bachelor of Science in Civil Engineering. Sixteen years afterward the University made recognition of his engineering achievements by conferring upon him the honorary degree of Doctor of Engineering.

Mr. Bush's early experience was on railroad and structural engineering in the West. Several years were spent on railroad location, construction, and maintenance on the Wyoming Division of the Union Pacific Railroad Company and with the Pacific Short Line Company in Wyoming and Utah. After a year in the bridge office of Morison and Corthell in Chicago, he served five years as chief draftsman and office engineer for the Pittsburgh Bridge Company in its Chicago office, followed by three years as engineer on the design of masonry for the bridges of the Chicago Sanitary District and as assistant bridge engineer and acting division engineer for the Chicago and North Western Railway Company. In the latter position he had valuable experience in moving the Kinzie Street drawbridge in Chicago and the Kinnikinnic drawbridge in Milwaukee, Wis. In these various ways he served an apprenticeship, grew in stature, and developed his powers to take larger responsibilities.

---

[1] Memoir prepared by a Committee consisting of C. A. Mead, M. Am. Soc. C. E. (Chairman), C. W. Hudson, M. Am. Soc. C. E., and H. S. Crocker and the late A. N. Talbot, Past-Presidents and Hon. Members, Am. Soc. C. E.

Then in January, 1900, came the opportunity to join the headquarters staff of the Delaware, Lackawanna and Western Railroad Company in Hoboken, N. J., as bridge engineer. This railroad was just entering what proved to be an era of tremendous betterments—with an extensive program of new structures and line improvements; heavier, stronger, and safer steel bridges; shortened and straightened alinements and greatly reduced grades; elimination of highway grade crossings in its suburban territory; and improved station, shop, and terminal facilities. Altogether this was a most promising prospect for an ambitious man. In less than a year Mr. Bush was principal assistant engineer as well as bridge engineer. In two years more he became chief engineer of the Lackawanna Road. In his nine years of service with this railroad, many improvements were completed and many others planned.

With a view of entering a larger field, in January, 1909, Mr. Bush established an office in New York, N. Y., as consulting engineer. Thus he was able to give expert engineering service on arbitrations, grade eliminations, foundations, bridges, and other large projects. Also, as a member of large construction contracting companies and carrying the heavy responsibilities as chief engineer of these organizations, Mr. Bush became a conspicuous figure in the construction of notable engineering structures.

He was vice-president and chief engineer of F. M. Talbot Company, Contractors, 1910 to 1917; president and chief engineer of Talbot Construction Company, 1911 to 1913; vice-president, chief engineer, and treasurer of Flickwir and Bush, Inc., 1912 to 1916; and president of Bush, Roberts and Schaefer Company, 1920 to 1925.

The engineering feats of Lincoln Bush are characterized by boldness as well as caution, by ingenuity and research, and by detailed planning and extracts from experience. At times he undertook daring procedures unprotected by precedent, and again, he resorted to plodding computations based on prior practice and experience. Any one who studies his work will be stirred by the appearance of novelty, by the daring and magnitude of a feat; he will marvel at the caution and care, the foresight and multitudinous provisions against failure, that were considered in advance.

The element of novelty in design and construction characterized his work. The Bush train shed, in use by many railroads, is an example. He originated and patented this construction. His many and varied engineering structures and constructions, in their nature and variety, would fill a large catalog. An idea of some of his work may be given by referring to an unusual project successfully completed a few months after he became chief engineer of the Lackawanna Road.

This feat, which drew the headlines of New York newspapers, was the removal of a 1,000-ton bridge truss to a new position against the odds of time and tide and weather. This four-track, double-deck swing bridge had been constructed the year previous for provisional use over the Passaic River, at Newark, N. J., preliminary to track-elevation construction. Permission from the United States War Department to obstruct the navigable waterway for the duration of one tide, twelve hours, was obtained for Sunday, December 20, 1903. Barges carrying immense sand jacks were placed under the truss, so that the incoming tide and removal of water ballast lifted the bridge from its support. Thus it was towed upstream to the new location for which it was designed. Reversing the action of the sand jacks and the water ballast, the truss was successfully lowered into its position on the now pivot pier, the barges were removed, and all traffic was resumed within the time limit before the turn of the tide would have lifted the burden again.

Sand jacks had previously been used for minor purposes. Mr. Bush, however, had to create his mode of procedure, learn the characteristics and eccentricities of sand jacks, and make his own precedents. Months were spent with experimental jacks and their operation. Provisions for pumps and boilers and duplications for emergencies were made. The variabilities of the tide and the currents had been given careful study; and it was well that this had been done, for that day the heavy rain, the tide, the wind, the current of the river, and the weather conditions formed as unfavorable a combination for such an undertaking as would probably ever occur. The next day, Monday, 200 passenger trains and 40,000 commuting passengers sped over that bridge as though it had always been there.

Mr. Bush's many achievements in engineering construction of large scale are well exemplified by the part he took in the building of the mammoth Tunkhannock Viaduct for the Lackawanna Road. This double-track viaduct is 240 ft high above the bed of Tunkhannock Creek north of Scranton, Pa. It consists of ten 180-ft arches of concrete masonry and two of 100 ft. The conception, design, and construction of the viaduct were under the direction of George J. Ray, M. Am. Soc. C. E., at that time chief engineer of the Delaware, Lackawanna and Western Railroad Company. Mr. Bush, as vice-president and chief engineer of Flickwir and Bush, Inc., Contractors, had the responsibility for the methods, equipment, and engineering procedure adopted and used in the entire construction of the viaduct and for the constructional progress of the work.

Many older members of the Society will remember that this structure, then well along toward completion, was the main objective of a most enjoyable all-day inspection trip, by special train on the Lackawanna Railroad, on the occasion of the Annual Meeting of the Society in January, 1914. Towers and cableway, transportation of materials, steel truss arch centers and their transfer, the conveying of concrete—these and all other details and ensemble were in Mr. Bush's hands. The speed, economy, certainty, and quality attained in the construction of one of the great masonry bridge structures built up to that time redounds to the constructive talents of Lincoln Bush.

The service he contributed to his country during the first World War is worthy of emphasis. With his long experience in construction and in the management of men, and with his knowledge of both rapid procedure and permanent construction, he gave loyally, unselfishly, and unreservedly of his professional knowledge, administrative skill, and driving energy. As an Officer in Charge of the Engineering Branch, under Gen. R. C. Marshall, Jr., M. Am. Soc. C. E., chief of the Construction Division of the United States Army, he was in responsible charge of the design and plans for practical operation for the seven terminal ports at Boston, Mass., Brooklyn, N. Y., Port Newark, N. J., Philadelphia, Pa., Norfolk, Va., Charleston, S. C., and New Orleans, La.; for fourteen interior warehouses located at industrial centers; for three arsenals; and for innumerable miscellaneous projects at other points, altogether totaling in cost $234,000,000. He entered the service in October, 1917, was commissioned Major in January, 1918, Lieutenant-Colonel in March, 1918, and Colonel in August, 1918. He assisted in harmonizing the work done by employees within the Division and with other branches of the service and also assisted in building up personnel of the Engineering and Construction divisions largely from his former associates and employees on engineering work.

His superior officer, in an official communication, reported that the services of Colonel Bush were regarded as invaluable to the success attained by the Engineering Division; that he had displayed most unusual qualities of engineering genius, sound judgment, and quick decision, and deserved the highest commendation; and that he was indefatigable in his application to duty, sound in his judgment, unremitting in his zeal, and successful in the achievement of a task of almost unprecedented magnitude.

Colonel Bush did his "bit" in helping win the war. When it was over and questions were raised regarding the conduct of the engineering construction, he was just as ardent in defending what he thought was right. In his private relationship and before congressional investigators he sprang loyally to the protection of the accused engineers from civilian life. Thereafter he maintained a great, although restrained, pride in his accomplishments during the war. Of all the titles and honors he received, he preferred to use that of "Colonel."

It is said that it is the duty of every professional man to contribute to his profession in a concrete way. This was true of Colonel Bush in his acceptance of office in the Society. He was Director for three years, 1912, 1913, and 1914; Treasurer for two years, 1915 and 1916; Vice-President for two years, 1924 and 1925; and President for one year, 1928.

In addition, after the untimely accident and subsequent death of Secretary John H. Dunlap on July 29, 1924, Colonel Bush gave daily counsel and advice in the administration of the affairs of the Society—over a period of a number of months—until a new Secretary assumed office the following January. He was never designated as Secretary or as Acting Secretary, but he nevertheless performed many functions of the office. From this standpoint, it may be said that he was the only member in Society history who had had personal experience in all the main offices of the organization.

Colonel Bush treated his election to office not as a mere honor, an empty recognition, but rather as an opportunity for service, a call to duty. In every instance he gave lavishly of his time and energy. One case stands out as a special evidence of his great loyalty to the Society. When Secretary Dunlap was fatally injured, in 1924, in the service of the Society, he took personal charge of Mr. Dunlap's interests. He assumed the responsibility of safeguarding Mr. Dunlap's estate, saving the family thousands of dollars. Colonel Bush's accomplishment was acknowledged by the Board of Direction at its meeting on October 22, of that year, when it adopted a formal vote of thanks for the great sacrifice the Colonel had made in stepping into the breach and rendering this valuable service.

From 1928 to 1932 Colonel Bush was consulting engineer for the City of Elizabeth, N. J. During this period the major project for the separation of grade crossings between the city streets and the tracks of the Central Railroad Company of New Jersey was being developed.

Colonel Bush was an outstanding member of the Society. He was also a member of the American Railway Engineering Association, the Western Society of Engineers, and the Engineers' Club of New York. He was the author of several articles that have appeared in the leading technical journals.

On financial matters his assistance on behalf of the Society was repeatedly sought. Among others, he served on the Board of Direction's Committee having responsibility for the 57th Street property. Here again, his financial insight and his thoroughness were of untold value to the Society. After he had convinced himself of the possibilities of this Society investment, he was adamant in his support of the course of action that to him was the only proper one. As a result, the Board approved of making a long-time lease of this property, a solution of great and lasting benefit to the organization. This case is only one instance, although perhaps the greatest, illustrating the many ways in which the Society has profited by Colonel Bush's financial intuition.

On October 17, 1890, he was married to Alma R. Greene, of Colfax, Ill., who, with their two sons, Cedric Lincoln and Denzil Sidney, survives him.

Of all Colonel Bush's noble traits, that of character stands out preeminent. He was as rugged and as dependable as the old log cabin home where he first saw the light of day. To his many intimate friends he was known to excel in forthright honesty and fearlessness. He was loyal to them and never hesitated to support them when they were attacked. He was persistent, painstaking, logical, and thorough. When he finally reached a conclusion, his judgment was similarly stable and complete. He would not be the first of a group to form a final opinion; but once formed, no man could hold a more rational one or defend it more reasonably. In this characteristic of dogged determination for what was right lay one key to his great success as an engineer and to his invaluable attributes as a man.

Colonel Bush was elected a Member of the American Society of Civil Engineers on October 4, 1905, and an Honorary Member on October 3, 1932.

DONALD HUBBARD SAWYER, Past-President, Am. Soc. C. E.[1]

DIED JUNE 21, 1941

The memory of Donald Hubbard Sawyer lives after him and is perpetuated in his lasting accomplishments, which, in retrospect, afford the truest measure of his stature. The lives of those who have known and loved him, and been associated with him, have been fuller and richer because of his inspiring influence. To countless of those who may not have been so favored, the record of his high professional ideals and noteworthy achievements will be a stimulant to higher aspirations and nobler efforts. Since June, 1941, he has rested in Arlington Memorial Cemetery beneath the canopy of the open sky, unmindful of sunshine or storm, drought or flood, peace or war. Amid the hectic turmoil of international strife, the knowledge that he has found eternal serenity carries with it the solace of a benediction.

---

[1] Memoir prepared by W. E. Reynolds, *Chairman*, and Daniel C. Walser and John C. Hoyt, Members, Am. Soc. C. E.

He belonged to the ninth generation of Sawyers in the United States. His paternal forbears came to America from England and settled in the New England states. The three generations immediately preceding him were born in Chester, Vt. His grandfather, having the pioneer spirit, moved to the West, and his father, George Silas Sawyer, settled at Mount Pulaski, Logan County, Ill., almost in the center of that great state, where he met and was married to Phoebe Content Hubbard. Donald Hubbard Sawyer was born there on August 26, 1878.

When he was six years of age, his parents moved to Oak Park, Ill., where Don attended the public schools and was graduated from high school in 1897. Already attracted to the profession of engineering, he spent a year with John W. Alvord, Hon. M. Am. Soc. C. E.—even at that time an eminent engineer—and then entered the College of Engineering at the University of Illinois, in Urbana, from which he received the degree of Bachelor of Science in 1902.

Whether Don possessed the divine gift of prophecy, in his attraction to the profession of engineering in his early life, no one will ever know, but, looking backward over the years, it is now plain that the golden age of engineering dawned at about the time that he was born. In the span of sixty-two years, between his birth and his untimely death, engineering made greater progress and offered greater opportunity for scientific genius than had ever occurred before in any comparable period of time. Engineering achievement went far toward revolutionizing our way of living and profoundly affected the course of civilization itself. Don and his fellows in the engineering profession contributed substantially and importantly to the social and economic progress that has relieved life of much of its drudgery, broadened the field of opportunity for all, and raised the standards of living to levels far above the wildest dreams of even the "wise men" living at the time that he was born.

After his graduation from the University of Illinois, Don began, step by step, to lay the foundation of a notable engineering career in which he was destined to achieve distinction and exert a powerful influence. His first two years after graduation from college were spent with the late Alexander Potter,[2] M. Am. Soc. C. E., of New York, N. Y., on projects in New Jersey and Johnson City, Tenn., and as city engineer at Paris, Ill. For the following six years he was with the Illinois Traction System and advanced to the position of chief engineer in charge of interurban construction.

---

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 106 (1941), p. 1652.

Already well on the way to eminence in his chosen profession, Don Sawyer, in 1910, sought wider fields of opportunity in the Pacific Northwest. As a partner in the firm of Sawyer Brothers, he turned his talents to irrigation and power projects and general municipal engineering. This association continued until the outbreak of the first World War.

After the entry of the United States into the first World War, and because of the urgent need of the Army for skilled engineers, Don Sawyer answered the call of his country and was commissioned a Major in the Construction Division of the Quartermaster Corps. He was in charge of the construction of Camp Grant, at Rockford, Ill., and built a nitrate plant at Cincinnati, Ohio, and another army cantonment—Camp Bragg, at Fayetteville, N. C. His success in these undertakings is attested by his promotion to Lieutenant Colonel and his retirement after the war with the rank of Colonel in the reserves.

When he returned to civilian life, he became associated with James Stewart and Company, of New York City. Two years later he was appointed secretary of the Associated General Contractors of America. After filling this office for seven years, he was made secretary of the Heating Board of Trade of New York. In 1931 the United States government again sought his engineering services, and from that time until his death he served successively as director of the Federal Employment Stabilization Board, president of the United States Housing Corporation, and chief of the Real Estate Section, Public Buildings Administration. When, to combat the depression, the Public Works Administration was created to launch a great program of public construction to set the wheels of industry moving again, he was designated by the President to act as temporary administrator of public works. After serving as vice-president of the Washington Building Congress, Colonel Sawyer was elected president of that organization but his death prevented his induction into office.

Other honors, too, were his. They are duly recorded in *Who's Who in America* for 1940–1941 and *Who's Who in Engineering* for 1941. There is no need to repeat them here, for great as were his engineering achievements, generous as were his sacrifices in the interest of his profession (particularly among students and junior engineers), and richly deserved as were the honors heaped upon him, it is upon Don Sawyer the man, rather than upon Don Sawyer the engineer, that memory lingers. It is upon the charm of his personality, his sincere affection for his friends, and his unswerving loyalty to them and to all who were associated with him that our thoughts dwell today.

The distinguished public service that Don Sawyer rendered is now a matter of recorded history, but he did something more important than that. He added to the sum of human happiness and joy. He was eyes for the blind, strength for the weak, and a shield for the defenseless. He embodied all the refinements of a brilliant mind, a chivalrous soul, and a heart as big as humanity itself.

He was a gifted public speaker, with an analytical mind, a ready wit, and a fine sense of humor. As such, hundreds outside the circle of his close friends came to know and admire him. It was in the intimacy of his home, however, that he was at his best. He and his wife, Elizabeth Osborn Merriam, to whom he was married on September 25, 1929, were the kind of friends before whom it was possible to think aloud. The real ornaments of his home were the friends who frequented it, for Don Sawyer loved people and this affection was universally reciprocated.

His professional engineering activities were conducted in a thorough, efficient manner, in which he showed the high administrative and organizing ability for which he was well known and highly respected. His sound judgment on engineering, financial, and other questions was fully recognized and sought for by those connected with his various activities. His tact and firmness in handling difficult questions were appreciated by all who came in contact with him.

To have known Don Sawyer, to have been favored with his friendship, to have been entrusted with his confidence, are things of a value that can be neither fully measured nor set down in cold type. Few men had more real friends than he and few men were accorded more generous affection by those who knew him best.

He is survived by his wife and two brothers, George L. Sawyer, M. Am. Soc. C. E., and Fred Sawyer.

Colonel Sawyer was elected an Associate Member of the American Society of Civil Engineers on April 6, 1909, and a Member on November 25, 1919. He was a Director from 1926 to 1928 and Vice-President during 1935 and 1936. The Society honored him by choosing him as its President in 1939, one of the youngest men ever to hold that high office.

ALEX DOW, Hon. M. Am. Soc. C. E.[1]

Died March 22, 1942

Alex Dow was born in Glasgow, Scotland, on April 12, 1862, the son of a Highland family whose members for generations had been skilled iron workers. His father was an expert accountant but had served an apprenticeship at the forge.

Young Alex attended the school of a Scots Presbyterian parish for six years, closing, at the age of less than twelve years, the only formal education he ever received. The rest of his education, his knowledge of the world's great literature, of science, economics, commerce, and his thorough and intimate knowledge of engineering, he gained himself.

---

[1] Memoir prepared by Alfred C. Marshall, M. Am. Soc. C. E., James W. Parker, Vice-Pres. and Chf. Engr., Detroit Edison Co., Detroit, Mich., Harry A. Snow, Controller, Detroit Edison Co., J. H. Walker, Engr. Asst. to the General Manager, Detroit Edison Co., and Henry E. Riggs, Past-Pres. Hon. M. Am. Soc. C. E.

As a boy his ambition was to become a marine engineer, but circumstances forced him to go to work at the age of eleven years, first as a messenger boy, later as junior clerk and stenograher in a railroad office. At the age of seventeen he was employed by the Cunard Steamship Line in Liverpool, England, in a clerical capacity which often caused him to be afloat. On such trips he spent all his spare time in the steamship engine rooms.

In November, 1882, in his twenty-first year, he came to the United States and was first employed by the Baltimore and Ohio Railroad Company. Then he became a supervisor of local line and instrument maintenance for the Baltimore and Ohio Telegraph Company and began his study of electricity. In October, 1888, he was employed by the Brush Electric Company of Cleveland, Ohio, organized by Charles F. Brush. His first assignment for that company was as installing electrician of the Chicago, Ill., office.

In 1889 he became district engineer of the Brush Electric Company at Chicago, and was responsible for the design and construction in 1892 of the lighting of the South Park system of Chicago, a job which involved the placing of thirty miles of underground cable.

Detroit, Mich., was then (1893) a city of 260,000 inhabitants. The Public Lighting Commission had been organized and was about to install a municipally owned electric plant. Mr. Dow was employed in 1893 as municipal engineer at a salary of $3,000 per year. He designed the plant and placed it in commission at an expenditure of $600,000.

In 1896, being convinced that private ownership is more efficient than public ownership, and having had enough of municipal employment, he resigned his position with the Public Lighting Commission to become Vice-President and General Manager of The Edison Illuminating Company of Detroit. When The Detroit Edison Company was formed in 1903, Mr. Dow was appointed to the corresponding position in the new organization with the same title. In 1912 he became President and held that position until 1940 when he retired and became Chairman of the Executive Committee. In this capacity he was actively engaged as adviser and counselor in the affairs of the company until his death.

During these years of service with The Detroit Edison Company, Mr. Dow was called twice to serve the City of Detroit. From 1916 to 1921 he served as engineer member of the Detroit Board of Water Commissioners, and again, from 1925 to 1932, he was President of the Board. During these twelve years of service on the Water Board, all of them years of immense expansion of plant and construction of major improvements, Mr. Dow not only protected the department from politics but devoted much time to study of the engineering problems and to developing and establishing the sound business procedures which have made this one of the outstanding water works properties of the nation.

In 1932 he was appointed civilian chief of the Detroit Ordnance District, War Department, a post whose duties he was particularly fitted to discharge both because of his technical knowledge and his keen interest in ordnance manufacture. Traveling privately he inspected arsenals in the United States, Canada, England, and France to learn first-hand the exacting requirements of shell manufacture. Returning with considerable knowledge of the subject, he initiated the development by the Ex-Cell-O Corporation of Detroit, of the special purpose shell-turning machine now in use in considerable numbers in the United States and Canada. That first machine was built by private subscription and presented to the United States government by way of demonstration. It was but one of his many contributions toward improved methods both in production and in contract procedure. He held the position until his death.

The preceding paragraphs give the chronology of Mr. Dow's professional career, but they fall far short of telling the complete story. He was a great engineer, a great executive, a great public servant, and above all, a great man and citizen who can never be replaced in the public life of the State of Michigan or in the hearts of those who knew him.

During the more than forty-five years of his connection with the Detroit Edison properties he never ceased to keep the closest contact with engineering problems or to be in a very real sense the active head of the engineering activities. Space does not permit a listing of the major problems. Their magnitude and importance are indicated by the statement that when Mr. Dow first joined the company in 1896 its total fixed capital was $389,000, and at the end of 1941 it was $341,652,000. The total utility earnings of the company were $149,000 in 1896 and lighting rates were four times greater than they were in 1941 when the revenues were $73,575,000. During these forty-five years the number of customers increased from 2,500 to 743,086 and the total output from 2,700,000 kw-hr to 4,319 million kw-hr. These figures give some idea of the magnitude of the problems of design, construction, and administration for the correct solution of which he was responsible. They also indicate clearly that the destiny of the property, which depended upon the accuracy of his decisions, was safe in his hands.

In 1896 there were half a dozen little electric light companies in Detroit in cut-throat competition for business. The Edison Illuminating Company was one of them. Mr. Dow decided that he would not give special discounts to gain or hold business; that all customers should pay the same rates for the same service; that the service should be as good as he could make it; that rates should be as low as possible. The wisdom of that decision is not only proved by the fact that his company survived and absorbed all of its competitors, but is abundantly proved by the figures of growth just cited.

The outstanding fact found in any study of Alex Dow's career and of his writings is that he kept ahead of the industry through wise decisions, some of them made years before their general acceptance.

In 1896 he wrote "A Frequency of 60 cycles is best for central station use." Certain other utilities adopted 25 cycles and are cursed with it, as it would cost millions of dollars to change over now.

In 1898 he inaugurated the differential rate for electric service, under which the liberal use of electricity was encouraged by a low follow-on rate after a relatively high charge for the first few kilowatt-hours. In 1902 Mr. Dow recommended to his directors that a new alternating current turbine-driven generating station be built with an ultimate capacity three times the total capacity of all the engine-driven generators then in service in the city. Turbines were then new and untried; today reciprocating engines are obsolete. When Delray Power House No. 2 was built, Mr. Dow decided to use boilers which were nearly five times the size of those in Power House No. 1, and they were much larger than any boilers in use anywhere. Today large boilers are in general use, but Mr. Dow was the courageous pioneer who first blazed the way.

In 1898 Mr. Dow was probably the first man in the United States to propose that electric utilities operate without competition under commission regulation. He wrote, "Two electric lighting plants in the same territory is an economic error * * * competition is to the detriment of the public * * * in the absence of competition it is necessary that prices be approved by a competent authority." Nine years later the Michigan Railroad Commission was given jurisdiction over electric rates.

In 1908 he insisted that no dividend be paid to stockholders unless an equal sum were set aside to start a reserve against the depreciation of plant. This was recognition of the need of reserves for the replacement of property years before the practice became general. The annual reports of the Bell Telephone Company discussed the subject at length in 1911 and later years. The Detroit Edison policy of reserves has not been founded on formula but has been wise and conservative. Mr. Dow expressed it in a letter in 1932 as follows:

> "My disagreement with you does not mean that I accept the foolishness of the doctrinaires who persist in teaching that each year of our Lord is a person-at-law having rights and sanctions as against every other year in respect to accruals for depreciation, whether the same be proven by inspection or be estimated by some scholastic formula. I insist on providing for accruals which I know must inevitably accrue. But I propose to follow the rule which was good business when Joseph was Grain Controller for old Rameses—namely to make the good years contribute to reserves or to betterments which will maintain value, and to let the lean years travel into the past without marking them as defaulters."

In 1912 Mr. Dow laid the foundation for the "Original Cost" property records of The Detroit Edison Company. Twenty-five years later the Federal Power Commission officially adopted "Original Cost" and ordered all utility companies coming under its jurisdiction to revise their records.

In 1915 he wound up the "Holding Company" phase of The Detroit Edison Company's existence, being of the opinion that the simplest possible corporate structure has advantages outweighing any possible benefits of indirect ownership. Since then the company has conducted its business directly instead of through subsidiary distributing companies. Not until twenty years later did Congress enact the death sentence for holding companies.

In 1915 the new tungsten lamp promised light for less than half of the electricity required by the old carbon and gem lamps. Some managers, fearing loss of revenue, opposed its adoption. Mr. Dow, taking the ground that opposition to an innovation that promised to be for the public good was un-ethical and futile, offered to and did replace burned-out lamps of the old type with new tungsten lamps. The old types are now completely obsolete.

In 1932, when times were bad and work was scarce, Mr. Dow adopted the forty-hour week a full year before the federal statute was enacted.

During his whole administration decision after decision was made, important decisions fundamental to the welfare of his company. Enough cases have been cited to indicate that they covered not only engineering but finance, public relations, rates, labor and economic problems, from one or two to twenty years ahead of public acceptance. There were undoubtedly some mistakes, but Mr. Dow was right far more than half the time.

Mr. Dow's whole philosophy of public utility management was so admirably expressed in a letter written in 1914 to a woman stockholder that we quote from it as follows:

> Your line of reasoning (as I follow it) leads you inevitably to your stated conclusion as to dividends and wages; that whatever is added to the one must be taken from the other. This conclusion is wrong * * *. The big mistake is the assumption that a manager, or operator, or manufacturer has a duty to stockholders or has accepted a trust from them which debars him from doing his duty to his own employees and to humanity as a whole.
>
> * * *
>
> "I have refused consistently to make long time contracts or agreements fixing rates and, while I have reduced rates, I have been able to increase the payment to labor per *unit of time* because I was simultaneously reducing the cost of labor *per unit of production.* Whereas, if my industry had already been highly developed and systematized when I took charge of it, so that no economies of organization or machinery were possible, I should have been unable thus to increase the day's pay of the men, unless I had been permitted to raise the selling price of my product to consumers. That I would have been able to do so is inconceivable. Even though I might have had legal right and governmental consent, any material rise in price would have made my product unmarketable. In all these years I have held that the duty lay upon me to protect not only the interest of my stockholders but those of my employees and to so manage my relations with the public which purchases my product that while the public was well served and got relatively low prices, it nevertheless paid enough to let me distribute a fair return to stockholders AND a satisfactory wage to employees. To do this with fair dealing between the three parties—Capital, Labor, and Public Service—has not only been my first duty but my whole duty. Because all the other duties merge into this."

His successor, and close associate, A. C. Marshall, M. Am. Soc. C. E., writes of him:

> "Mr. Dow was a great man in so many ways that it is impossible to know at this time what particular facet of his brilliant mind will be remembered the longest, or what particular trait of his lovable nature will be treasured the most—because right now the sense of personal loss is overwhelming. * * *
>
> "As time goes on, we will think of other characteristics of his greatness. We will think of his knowledge of history—his grasp of ancient as well as modern philosophy and religions—of his knowledge of and love for the King James version of the Bible, and of his high standing in the

field of pure science—physics and astronomy. All of this in addition to his recognized position as an authority in economics, finance and religion.

"He was, in a true sense, a gentleman and a scholar. To know him and to work with him was a liberal education."

H. A. Snow, Controller of The Detroit Edison Company, and his long associate, in closing a summary of Mr. Dow's career, writes:

> "How was it accomplished? By luck? No—the percentage of accuracy was far too high. By intuition? Perhaps—he claimed, smiling, some acquaintance with the pixies. By high intelligence? Certainly. His was undoubtedly one of the best minds in the Nation. By character? Yes! His motto was live and let live. He had no great use for personal wealth—money was something to be spent, freely, joyously. By hard work? Of course. The forty-hour week was for his men—not for him. His appetite for information was insatiable. * * * His mastery of the English language was unequalled, and his writing had a clarity and brevity and charm that could only come from the mind of a man such as he.
>
> "He dealt on somewhat better than even terms with specialists in a dozen lines of human thought—he outfigured engineers and outtalked lawyers; he expounded theories to professors and theology to parsons; he fearlessly raided predatory politicians and he out-bargained financiers. Now it is better than even money that he is showing Charon how to row.
>
> "This imposing record of accomplishment, with its undeniable proof of intelligence and ability may account for the respect but it does not account for the affection with which he is remembered by the ten thousand men and women who make up his staff. After years and years of being praised and reprimanded and bulldozed by him, a deep feeling of personal loss comes to all of us at his death."

Mr. Dow was an Honorary Member and Past-President of the American Society of Mechanical Engineers; Fellow and Honorary Member of the American Institute of Electrical Engineers; Member of the Institution of Electrical Engineers (Great Britain); Member of the Institution of Mechanical Engineers (Great Britain). He was one of the founders of the old Detroit Engineering Society, and was an Honorary Charter Member of the Engineering Society of Detroit; member and past chairman of the Rates Committee National Electric Light Association; and past-president of the Association of Edison Illuminating Companies. He was awarded the Edison Medal by the American Institution of Electrical Engineers in 1936.

Since 1936 Mr. Dow has been President of the Trustees, Rackham Engineering Foundation.

In 1911 the University of Michigan, at Ann Arbor, conferred on him the Honorary degree of Master of Engineering, and in 1924 that of Doctor of Engineering. He was given the degree of Doctor of Science by the University of Detroit in 1936; and the degree of Doctor of Arts by Wayne University (Detroit) in 1938.

Alex Dow was married in 1889 to Vivia Kinnersley of Baltimore, Md., who survives, together with their four children, Lothrop Dow, Col. Douglas Dow, Dorothy (Mrs. James W. Parker), and Margaret (Mrs. Lawrence H. Connell).

After a full life that had brought him more than the usual satisfactions for which men live, he left this world as he would have wished, working actively until Friday, March 20 when he went to the hospital. He passed away in his sleep on the following Sunday morning.

Mr. Dow was elected a Member of the American Society of Civil Engineers on December 5, 1906, and an Honorary Member on October 11, 1936.

THOMAS ULVAN TAYLOR, Hon. M. Am. Soc. C. E.[1]

DIED MAY 28, 1941

On the Texas frontier on January 2, 1858, a red-headed son was born to John Henry and Louisa (Allison) Taylor. This boy was christened Thomas Ulvan Taylor. His father died when he was about ten years old, and he had to help his mother make the living for the family. His mother was a wonderful woman, for she instilled into young Tom a burning desire to get an education. In spite of adversity, and poverty, he succeeded in doing this and as a result he has left his influence on the engineering profession in Texas and the Southwest.

The first school he attended was held under an oak tree. Indians were very common in that section of the state at that time, and the boys attending school carried rifles for protection; during school hours these rifles were stacked against the tree.

Railroads were just being developed in Texas. The Houston and Texas Central Railroad was being promoted north from Houston. As a young boy, Tom would accompany the freighters that went to the depot—the end of the railroad—Hempstead, Navasota, Hearne—to get supplies and haul them inland. Also, he made trips to Jefferson, Tex., which was the terminus of navigation at that time. Steamboats would come up from the Mississippi River, the Red River, and through Caddo Lake to discharge their cargoes at Jefferson. The freighters would carry this merchandise to the inland towns and forts.

When he was twelve years old he went to Cleburne where he obtained work in a brickyard "trotting brick." He supplemented his income by getting up early in the morning and carrying water from a spring to the saloons for five cents per bucket. He enjoyed telling of the arrival of the stage coach; this occurred about 4 o'clock each morning. The driver of the coach was provided with a long tin horn, and as he approached the town he would blow several long, loud blasts on this horn to announce his arrival.

When he was about fourteen he went to live with an uncle in Fannin County. Here, he worked on the farm and did other chores. He made friends with an older man, who coached him in his school work—in effect he had a private tutor. In 1879, the Sam Houston Normal, in Huntsville, Tex., opened its doors. The first students were selected by competitive examination and T. U. Taylor won first place in a group of eight from his senatorial district; he was admitted to college. His thirst for knowledge was increased; after graduation from college, when his uncle offered to lend him the money to buy a farm and a pair of mules, young Taylor borrowed the money, but he went to the University of Virginia, at Charlottesville, Va. He was graduated from this institution in 1883, after two years, with a degree of Civil Engineer. Here, he came in direct contact with famous characters of the Civil War days. He was so thoroughly saturated with the "Honor System," as it existed in the University of Virginia at that time, that he believed in it to the very last. He made such an excellent record at Virginia that he was offered a place teaching physics and mathematics at the Miller Institute, Crozet, Va., where he stayed for five years.

---

[1] Memoir prepared by John A. Focht, M. Am. Soc. C. E.

An opening developed at The University of Texas, in Austin, for a teacher of Mathematics, and he could not resist the call to return to his native state. He joined the faculty of The University of Texas in 1888, and he continued there until his death. There were thirteen on the faculty and about two hundred and fifty students when he came to the University. In 1895, the Department of Civil Engineering was created and he was made Dean. This position he held for forty-one years; in 1936 he was retired as Dean Emeritus.

He was deeply interested in the welfare of his boys. Not only did he keep up with the boys' work in school, but he also knew about their financial conditions and their love affairs. He had a wonderful memory and recalled names and incidents easily. Many a man has walked into his office after an absence of twenty, twenty-five, or thirty years; Dean Taylor would look up from his work, push back his glasses, and call the man by his nickname, throw in his middle name for good measure, and then start talking about school-boy pranks and affairs in which this individual had been involved. He had an obsession to help the poor boy who was struggling financially to make his way through school. At first he would lend to the students from his own pocket, but as time went on he established Loan Funds which took care of the financial needs of the students. First came the Engineers Loan Fund with a Board of Trustees; to borrow money from this fund the student must have a "C" average. The Dean realized that there were worthy boys who did not have the "C" average, so he established the Big Brothers Fund, and he administered this Fund without consulting any one. He was always quick to say that during the entire time he had dealt with students he had never lost one penny—the loans had always been repaid.

Some four years ago Dean Taylor provided funds for a Foundation; cash awards are made to some six or seven senior engineers each year from the income of these funds. No applications are made for these awards, but the Board of Trustees makes inquiry as to worthy students to receive these awards. Dean Taylor definitely specified that they be given to seniors who, during the fall semester of their senior year, earned part of their college expenses by the sweat of their brow—such jobs as waiting on tables, washing dishes, carrying a paper route, etc., were acceptable, but white-collar jobs such as grading papers, office work, etc., were not to be considered.

One night, in 1905 or 1906, some of his students came to his house and reported that one of their classmates had withdrawn from the University, and was leaving on the night train for his home in East Texas. Dean Taylor went to the depot, and talked with the boy; his money was exhausted, and he was returning to the farm. The next morning this boy registered in the University—the Dean had taken care of financial troubles—and he completed his course with credit. This man is one of the prominent hydraulic engineers in the United States today.

In 1920, a young Russian refugee reported to Dean Taylor's office and inquired about going to school. After a number of questions Dean Taylor agreed to permit him to enter the engineering department. The boy admitted he had no money but his answer to how he would make his living was—"I can washa the dish." Dean Taylor helped him get a job, and kept close watch over him. In due time he was graduated with honors, having been elected to Tau Beta Pi. He became a prominent figure in oil refining. He became a naturalized citizen. Years elapsed. A delegation came from Russia to study oil refining and obtain technical help for some of their problems. He was finally persuaded to return to Russia to help solve some of their difficulties. Truth is stranger than fiction for he was sent as a consultant back to his home town, from which he had run away a few years before seeking opportunity in the United States. Just two or three years ago an organization in Texas offered a prize to high school students for the best paper on "Why I Am Glad I Am an American." The daughter of this Russian refugee whom Dean Taylor had befriended won first place in this state-wide contest.

He helped others than engineering students. One day the writer went to Dean Taylor's office immediately after lunch, and he found the Dean seated at his desk and a boy standing in front. The Dean asked the boy, "Will this be enough?" and the boy answered, "Yes Sir." The Dean filled out a check and handed it to him. After the boy had left, the Dean turned and said, "That boy is a student in the College of Arts; his funds were completely exhausted and it would be a week or ten days until his check came; he had no money to buy his meals; he did not feel close enough to any of his professors to ask for help, so he came to me." No one will ever know how many boys Dean Taylor helped in one way or another; he never let his left hand know what his right hand did.

Dean Taylor was a great favorite with the students; every one of the students who attended the University since 1888 knew him. This is illustrated by the fact that in the early stages of his last illness he went to a clinic in Temple, Tex., for examination. A young doctor came in the room and said, "Hello, Dean Taylor; you may not know me but I know you. I was a premed student at The University in 1930." Every year he was asked to speak at one of the principal football rallies. In 1923 when one of the Campus characters—a dog—died, an enormous parade was formed which marched around the campus to the front of the Main Building. From the front steps Dean Taylor delivered the funeral oration of this dog, which had been the pet of the entire student body for eight or ten years. Several have said that this was one of the best speeches Dean Taylor ever made.

Early in his teaching career, Dean Taylor was affectionately christened "The Old Man" by his students. More of his students referred to him by this title than any other. From the beginning Professor Taylor developed the habit of marking a perfect paper with a check mark rather than the customary 100. This check mark accumulated a flourishing tail. One day after the Professor had returned some papers, the students gathered in the hall to compare grades. One of the boys exclaimed, "The Old Man gave me a Ram's Horn." A tradition was born, and the name stuck. In 1913 when the Dean had been at the University twenty-five years—the first person to have that honor—he was given a banquet, and was christened by his former students as "The Grand Old Man." The Dean presented to every man present, and every man who had been a student under him during that twenty-five years, a brass watch fob with the inscription "The Old Man's Engineers, 1888–1913," and the embellishment of a Ram's Horn. At that time he said he was giving all of his students, and former students, a Ram's Horn.

In 1897, he was appointed hydrographer for Texas by the U. S. Geological Survey. At that time practically nothing was known about the discharge of streams in Texas. He established a number of gaging stations and arranged for observers to record the elevation of the water at least daily. At intervals, Dean Taylor went to these stations and made discharge measurements, from which rating curves were constructed. He was so interested in this work that when the government funds were discontinued he carried on the work for several years at his personal expense.

During this time he became interested in the silting of Lake McDonald, the first lake constructed on the Colorado River near Austin; he made periodic measurements on this and Lake Austin, and published several bulletins on the silting problem. He was an outstanding authority on the silting of reservoirs in the Southwest.

When he was more than seventy five, he organized a party of ten consisting of professors and graduate students and went to Lake Worth to make one of his periodic silting surveys of that lake. The party obtained a cabin at the lake, and the next morning he had the group out in the boats before sunup; the Old Man spent the entire day in a boat working as hard as, or harder than, any one else. After this survey was completed, he insisted that the party return home that night—more than two hundred miles. The next morning he was at his office as usual—seven o'clock.

Dean Taylor was an early riser; he was up and had his breakfast by daylight. His regular scheduled office hour was seven to eight in the morning. He always requested that his classes be at eight o'clock in the morning. When boys would miss a quiz or make an extremely low grade and ask for a makeup, he usually granted the request, but he would set the time for six o'clock the following morning.

In the summer of 1892, Professor Taylor was assistant engineer in the office of the late J. A. L. Waddell, Hon. M. Am. Soc. C. E., on the design of Inter-State Draw Bridge, and the Halstead Street Lift Bridge. In the winter of 1893, he assisted Mr. Waddell in the competitive design for a bridge over the Danube River at Budapest, Hungary.

Professor Taylor was called in a consulting capacity by a number of the Texas cities to assist in the solution of their water problems. Some of these cities were Austin, Abilene, Dallas, Fort Worth, and Wichita Falls.

Dean Taylor was a member of the Texas Academy of Science from its organization until his death. He was also an active member of the Texas State Teachers' Association, the Society for the Promotion of Engineering Education, the American Mathematical Society, and the American Association for the Advancement of Science. He was a member of Phi Beta Kappa, Tau Beta Pi, Chi Epsilon, Pi Tau Sigma, Pi Epsilon, and Eta Kappa Nu.

He was the author of a number of books including "Earthwork and Prismoidal Formulas," "Backbone of Perspective," and "Surveyors Handbook." He was the author of a number of Water-Supply Papers and Bulletins based on data gathered while working for the U. S. Geological Survey. In his later life he was interested in preserving the early history of Texas, and wrote "The Chisholm Trail and Other Routes," "Jesse Chisholm," "Fifty Years on Forty Acres," and innumerable articles on the life and happenings of early Texas pioneers.

He was married in 1888 to Maria Moon in Albemarle County, Virginia. He is survived by his widow, and one daughter, Julia (Mrs. D. C. Strother). A son, Dr. Summerfield M. Taylor, died in 1940.

One of the reasons for Professor Taylor working for Mr. Waddell in 1892 was to gain acquaintance with engineers who would give their names as references on his application for membership in the American Society of Civil Engineers. It is said there were not five members in Texas at that time. He was elected an Affiliate (then Associate) on January 31, 1893; an Associate Member on October 2, 1895; a Member on October 2, 1901; and an Honorary Member on October 6, 1939. He became a Life Member in 1928.

FRANK ELWIN WEYMOUTH, Hon. M. Am. Soc. C. E.[1]

Died July 22, 1941

Upon the Empire-building water conservation and development projects that have transformed vast wastelands of Western America into productive and populous areas since the turn of the twentieth century no mind or hand has made a deeper imprint than Frank Elwin Weymouth's. From the day in 1902 when the federal government launched its first reclamation project until his death on July 22, 1941, he ranked among the foremost of those who planned and directed the successful completion of the far-flung system of dams, canals, and conduits which now conserve and distribute for the service of Man the life-giving water of a score of great rivers in that boundless territory which old geography textbooks once marked out as "The Great American Desert."

---

[1] Memoir prepared by Julian Hinds, M. Am. Soc. C. E.

One of Mr. Weymouth's earliest engineering assignments as a young man fresh from the halls of his University was work in the planning of the Massachusetts Metropolitan Water District. In this task he gave his talents to America's first great publicly owned domestic water-supply system, designed to serve through a common effort the needs of numerous cities. Later, and for many years, he concentrated his remarkable engineering and organizing abilities on the government's gigantic irrigation and reclamation program. At the close of his career he had completed his greatest accomplishment—the planning and building of the Colorado River Aqueduct through which an abundant and unfailing domestic water supply has been made available to Los Angeles, Calif., and twelve other enterprising cities which comprise The Metropolitan Water District of Southern California.

Frank E. Weymouth was born in Medford, Me., on June 2, 1874, the son of Andrew Jackson and Charlotte Prudence (Powers) Weymouth. After finishing high school at near-by Fort Fairfield, Me., he took a civil engineering course at the University of Maine, at Orono, Me. He was graduated with the degree of Bachelor of Science in Civil Engineering in 1896, and subsequently honored by this institution with the degree of Doctor of Engineering in 1934. His first job after graduation was with the City of Malden, Mass., and later with The Metropolitan Water Board in Massachusetts, on water works construction, the field in which his greatest distinction was to be attained in later life. From this work he went to the City of Winnepeg as assistant city engineer, holding this office until June, 1899, when he joined the engineering organization of the Isthmian Canal Commission of the United States government and was engaged until 1901 in making surveys and studies in connection with the proposed Nicaraguan Canal.

In 1902, when the U. S. Reclamation Service was created, Mr. Weymouth joined its engineering organization and served with this bureau in various capacities and with ever-increasing responsibilities for the following twenty-two years. During his early years with the Service, he was in charge of surveys and investigations for irrigation projects in Montana and North Dakota. In 1908 he became supervising engineer in charge of the Idaho District, and in this capacity directed the design and construction of irrigation projects in the Snake River region, an engineering work affecting more than 400,000 acres of land. Among the important structures built under his supervision during this period were the storage dam on the Snake River at Jackson Lake, Wyoming, and the Arrowrock Dam, on the Boise River in Idaho. This latter dam, 349 ft high, was the tallest in the world at the time of its construction.

From 1916 to 1920 Mr. Weymouth served as chief of construction in charge of all work undertaken by the Reclamation Service in the Western States, and in 1920 he was made chief engineer of the Bureau, a post which he held until his resignation in October, 1924. During this period the Reclamation Service engineering organization, under Mr. Weymouth's leadership, was one of the pioneers in the development of new methods of dam design and construction, which culminated in the successful construction by the Bureau some years later of the Boulder Canyon Dam to a maximum height of 720 ft, more than twice that of Arrowrock, which stood unchallenged for so many years after its completion in 1915 as the "world's highest." Indeed, one of Mr. Weymouth's outstanding achievements as chief engineer of the Reclamation Service was his work, with the late Arthur P. Davis,[3] Past-President, Am. Soc. C. E., and at that time director of the U. S. Reclamation Service, on surveys and the preparation of plans and estimates for the Boulder Dam project. The "Weymouth report" furnished the basis of facts and figures upon which the final decision as to the feasibility of this project rested.

Upon leaving the Reclamation Service, Mr. Weymouth became president of the engineering firm of Brock and Weymouth, of Philadelphia, Pa. In 1926 he severed this connection to take the position of chief engineer of the J. G. White Engineering Corporation in Mexico, in charge of all engineering work being handled by that organization for the Republic of Mexico. In this capacity he worked with the National Irrigation Commission of Mexico and was in active charge of all the irrigation and reclamation projects that were carried forward during the administration of President Plutarco Elías Calles. This work involved extensive investigation of irrigation possibilities throughout the republic and the supervision of the planning and actual construction of a number of important projects. Notable structures were the Don Martin Dam near Nuevo Laredo and the Calles Dam in the State of Aguascalientes. There were several other dams and many miles of canals and laterals, with a variety of incidental structures. This work was completed with notable success and dispatch.

In 1929 Mr. Weymouth was retained by the City of Los Angeles as chief engineer of Water Works, and placed in charge of the Colorado River Aqueduct studies then being conducted by that city. Later in the same year he was appointed chief engineer of The Metropolitan Water District of Southern California, which had been formed to take over this project. In 1931 he was appointed to the position of general manager and chief engineer of the District, and became the District's chief administrative officer, as well as its chief engineer.

The Metropolitan Water District of Southern California is composed of thirteen cities located in what is known as the South Coastal Basin of California. This basin contains 45% of the wealth and population of the State of California and only 1% of the water resources.

The region is arid, and upon his arrival, Mr. Weymouth found that physical development had gone far beyond the safe annual yield of existing water resources, this condition having been made possible by seriously overdrawing the waters accumulated during prehistoric times in the deep gravel beds underlying the basin. The community was facing the alternative of bringing in a new supply from an outside source or of serious retrogression. The possibility of importations from near-by sources had been exhausted. The only possible origin of a new supply was the Colorado River, which lay 300 miles away and at the time lacked storage facilities required to conserve its variable flow for domestic diversion. The problem of tapping this river for the benefit of Southern California was committed to Mr. Weymouth.

---

[3] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 100 (1935), p. 1582.

Planning and building the Colorado River Aqueduct involved tremendous problems at every step of its development. The first task was the selection of the best route across a vast extent of desert, the geological and topographical details of which were practically unknown. Simultaneously, it was necessary to prepare preliminary estimates and to convince the voters of the District of the need for and the practicability of the project. That these tasks were well accomplished was evidenced on September 29, 1931, when a proposed bond issue of $220,000,000 was carried by a five-to-one majority.

Actual construction was started late in 1932 and the aqueduct was completed and delivering water to District cities on June 18, 1941, a month before Mr. Weymouth's death. The present development involves 242 miles of main aqueduct and 150 miles of laterals, or wholesale delivery lines—a total of 392 miles. Of this length, 92 miles is 16-ft-diameter tunnel and 16 miles is 10-ft tunnel. There are four important dams, five high-head pumping plants, 237 miles of high-voltage transmission lines bringing Boulder Dam power to the pumping plants, and all of the many miscellaneous structures that go with a project of this magnitude.

On December 3, 1900, Mr. Weymouth was married to Mary Maude Lane, who died on January 2, 1937. On November 10, 1938, he was married to Barbara Turner, who survives him.

For almost forty years Mr. Weymouth was engaged in responsible engineering work on large government projects. Early in his career he demonstrated the ability to deal effectively and cordially with members of Congress and ranking government department heads, and yet there was nothing of the politician in his character or his methods. He possessed a deep and abiding aversion to the "handshaking" and "back-scratching" technique of certain types of professional politicians, and steadfastly refused to permit such operators to interfere with or influence his public duties in any particular. Nevertheless, his unquestioned ability and his unshakable honesty won for him the support of responsible government heads, where, in many instances, the political maneuvers of others had failed.

He was a man with no personal hobbies outside the orbit of his professional work. Reading appeared to be his only relaxation. Biographical and historical works made up a large part of his non-technical reading. He carried his professional interests and his work with him into his home, where he spent long hours of almost every day in the review in minute detail of the reports of his assistants, and in the analysis of current problems.

One of the secrets of his outstanding success as an executive and an organizer was his uncanny ability to pick the right man for a particular task. To his subordinates he delegated ample authority to do the job, and at the same time he held each man strictly accountable for the success or failure of his work. As every successful executive must, he generally passed on to his aides the manifold details of an assignment, and yet these details never escaped him. Frequently he appeared to concentrate upon what, to others, appeared to be a minor phase of a problem under consideration. In such instances, it developed that the "minor phase" was the crux of the entire problem, a realization which sometimes dawned slowly and painfully in the minds of his assistants.

To the preparation of reports and written recommendations for specific action by governing bodies, he gave careful and meticulous attention. Such documents, he insisted, must be clear, accurate in all details, solidly buttressed with definite findings and incontrovertible facts. Once, twice, or a half dozen times any such report might come "sailing" back to the desk of a subordinate bearing the marginal suggestions and constructive criticisms of the Chief. It had to be right, not only in its general outlines but in every phrase and every single word; and not until it was right would it pass the barrier of Mr. Weymouth's desk.

Few men have given more of their waking hours to the daily tasks before them than Frank E. Weymouth. Behind him he has left an enduring record, in steel and concrete, of his accomplishments in the service of his fellow men. It has been the lot of few men to leave a greater record.

Mr. Weymouth was elected an Associate Member of the American Society of Civil Engineers on September 4, 1901; a Member on February 5, 1907; and an Honorary Member on October 10, 1938.

CHARLES MELVIN ADAMS, M. Am. Soc. C. E.[1]

DIED AUGUST 31, 1941

The passing of Charles M. Adams at the ripe age of 81 years removed a widely known and respected engineer from civil engineering activities in northwestern Washington.

Mr. Adams was born at Prattsburg, Steuben County, N. Y., on June 11, 1860. He attended public schools in Prattsburg and was graduated from the Franklin Academy, in Prattsburg, in 1878. Following graduation he taught in rural schools. Later, he taught mathematics for three years at the Franklin Academy, during which time he took up the study of civil engineering.

Mr. Adams' first engineering experiences were with the Western New York and Pennsylvania Railway Company and later with the Lackawanna and Pittsburg Railroad Company in New York State, and the Chicago, Burlington and Quincy Railroad Company in Illinois. From 1885 to 1888 Mr. Adams was division engineer with the Chicago, Rock Island and Pacific Railway Company in Kansas. He later held the same position with the New York, Pennsylvania and Ohio Railway (Nickel Plate) and the Toledo and Ohio Central Railway companies in Ohio, and the Lehigh Valley Railroad Company in New York.

He went West late in 1890, arriving at Whatcom, Wash. (later named Bellingham), on Thanksgiving Day. He was engaged as engineer on the

---

[1] Memoir prepared by C. N. Reitze, M. Am. Soc. C. E., and H. M. Hadley and M. S. Campbell, Assoc. Members, Am. Soc. C. E.

Bellingham Bay and British Columbia Railroad (Chicago, Milwaukee, St. Paul and Pacific Railroad) until completion of that line in 1891.

On three different occasions, 1892–1895, 1900–1901, and 1918–1924, he served Bellingham as city engineer, having charge of design and supervision of construction of paving, sewers, bridges, water works, etc. He also served Whatcom County as county engineer from 1895 to 1897, 1901 to 1905, and 1913 to 1917, having charge of the design and construction of the county's highway system, including bridges, river protection, and drainage works. Some of the earliest concrete pavement used in the State of Washington was laid by Mr. Adams during his last term as Whatcom County engineer.

From 1898 to 1899, Mr. Adams was construction engineer in charge of an extension of the Canadian Pacific Railway through the mountainous Kettle River district.

From 1927 to 1929, Mr. Adams served as municipal engineer for the government of the Dominican Republic, in direct charge of the installation of various projects totaling $3,000,000 and including the water supply system, storm and sanitary sewer system, and street paving of the capital city, Cuidad Trujillo. While in the Dominican Republic, he served as consultant for other projects of a similar nature. The West Indian climate, however, did not prove well suited to Mr. Adams, and following his return to Bellingham, his earlier good health deserted him. For the last eleven years of his life he was an invalid, confined quite closely at home.

Mr. Adams was a member of the Presbyterian Church, of the Prattsburg Lodge No. 583 F. and A. M., of New York, and of the Bellingham Elks Club. In May, 1888, he was married to Ida Belle Middleton of Prattsburg, who survives him, together with a son, John M. Adams, Assoc. M. Am. Soc. C. E.

Mr. Adams was elected a Member of the American Society of Civil Engineers on August 27, 1928.

LAYSON ENSLOW ATKINS, M. Am. Soc. C. E.[1]

DIED SEPTEMBER 17, 1940

Layson Enslow Atkins, only child of Abraham L. and Louise (Cummings) Atkins, was born in Hurleton, Butte County, Calif., on October 12, 1892. He was of Scotch and English descent.

Soon after graduation from high school at Berkeley, Calif., he was appointed to the United States Military Academy, at West Point, N. Y., from which he was graduated in 1915. He was then commissioned a Second Lieutenant, Corps of Engineers, and was enrolled as a student officer at Washington Barracks, District of Columbia, from September, 1915, to September, 1916, and again from January to April, 1917. His military education was further supplemented by studies at the Army Industrial College at Washington, D. C., in August, 1934, from which he was graduated in June, 1935. In August, 1935, he entered the Army War College and was graduated from it in June, 1936.

---

[1] Memoir prepared by B. C. Dunn, Assoc. M. Am. Soc. C. E.

His foreign military service commenced in 1916 with an assignment to Company B, 2d Engineers, during the Punitive Expedition into Mexico. From May, 1917, to March, 1918, he was Captain and Adjutant in the 14th Engineers, Railway, and was engaged in organizing and training troops in the operation and maintenance of light railways in France. From March to August, 1918, he was in charge of training of engineer candidates for commissions in the American Expeditionary Forces, and was senior instructor in the Bridge Section of the Army Engineer School at Langres, France.

On returning to the United States, his military duties were continued as Commanding Officer of the 9th Engineers at El Paso, Tex., from October, 1918, to September, 1919; and as Adjutant, 5th Engineers, at Fort Belvoir, Virginia, in 1920. In a later tour of duty with troops, from July, 1932, to February, 1934, he served as Commanding Officer of the 2d Battalion of the 6th Engineers at Fort Lewis, Wash.

From June, 1936, to July, 1939, Lieutenant-Colonel Atkins was Chief of the Supply Section, in the Military Division of the Office of the Chief of Engineers, in charge of procuring and furnishing engineering equipment to all components of the United States Army.

His ability as an instructor in military science was early recognized by his superiors and, as Major Atkins, he was associate professor of Military Science and Tactics at the University of Illinois, in Urbana, Ill., from August, 1920, to August, 1924, and served as instructor at summer camps at Fort Humphreys, Va., and at Camp Custer, Mich., during the same period.

During his career as an engineer officer, Lieutenant-Colonel Atkins fulfilled several assignments on civil works that are performed by the Corps of Engineers. It is somewhat difficult to record the professional engineering accomplishments of an individual engineer officer. In a sense he directs teamwork, and his personal contribution to engineering achievements, barring exceptional cases, is submerged in the mass effort of the team. To state that a man was assistant district engineer, or district engineer, does not mean much, but in order to convey an idea of the contribution of the officers and engineers engaged upon these works to the engineering achievements of the age in which we live, the following outline thereof is presented:[2]

Since 1820, the Engineer Department of the U. S. Army has been continuously engaged in the performance of various works on the navigable waters of the country and their tributaries. Its civil works in the field are effected through forty-seven districts grouped into eleven divisions. Each district and division is in charge of an officer of the Corps of Engineers assigned as district or division engineer. The Corps of Engineers is the federal agency responsible for planning, constructing, and, with some exceptions, maintaining and operating improvements for navigation and flood control on rivers and harbors of the United States, Alaska, Hawaii, Puerto Rico, and the Virgin Islands. Such improvements include breakwaters, canals, locks, dams, power houses, and accessory works. The department is also responsible for regulating the use of navigable waters and surveying the Great Lakes. Since its establishment, its officers have also been employed in municipal engineering and management at the Nation's capital. For several years, prior to 1932, roads, bridges, and trails were constructed in Alaska by the Alaska Road Commission, which was then directed by officers of the Corps of Engineers. In the performance of these civil works, engineer officers are afforded greater opportunity for contact with other professional engineers, and with the general public, than officers engaged in military duties.

---

[2] See "The River and Harbor Functions of the Corps of Engineers," by Thomas M. Robins, Brigadier General, U. S. Army, published in *The Military Engineer*, September–October, 1940, p. 325.

Lieutenant-Colonel Atkins' assignments in civic works constructed by the Corps of Engineers included two years, September, 1924, to August, 1926, as assistant to the district engineer of the Louisville, Ky., District; four years, September, 1926, to May, 1930, in Washington, D. C., as assistant to the engineer commissioner of the District of Columbia, where he was in charge of the municipal architect's office; two years, June, 1930, to July, 1932, at Juneau, Alaska, as engineer officer of the Alaska Road Commission and assistant to the district engineer on river and harbor projects; and finally, from August, 1939, he was district engineer at Seattle, Wash., until relieved on July 23, 1940, by reason of illness.

The Seattle Engineer District embraces most of the State of Washington, northern Idaho, western Montana, and the Territory of Alaska. During Lieutenant-Colonel Atkins' incumbency as district engineer, there were nineteen river and harbor projects and ten flood-control projects in active operation in the district. Among the latter was the White River project, then in its early state of construction, the principal feature of which is the Mud Mountain Dam. This dam is 425 ft above the lowest bedrock in the river—the highest rock-fill dam ever constructed. The original design contemplated an earth-fill dam, but change to the rock-fill type was made during his term as district engineer.

The career of Lieutenant-Colonel Atkins as an officer in the various grades from Second Lieutenant to Lieutenant-Colonel exemplified notably the principles of probity, honor, devotion to duty, and other characteristic ideals of the Corps of Engineers. A summary giving dates of his various appointments in the military establishment is deemed appropriate:

Layson E. Atkins was a cadet at the U. S. Military Academy from June 14, 1911, until June 12, 1915, when he was graduated and commissioned as Second Lieutenant in the Corps of Engineers. He was promoted to First Lieutenant on July 1, 1916, and to Captain on May 15, 1917. He was given a temporary commission as Major on February 18, 1918, which expired April 26, 1919, returning him to the grade of Captain. He was again promoted to Major on July 1, 1920. In accordance with Acts of Congress approved June 30, 1922, and September 14, 1922, relating to Army reorganization, he was discharged as Major and appointed Captain on November 4, 1922. He was permanently promoted to Major on January 22, 1924, and to Lieutenant-Colonel on May 1, 1936.[3]

He possessed a keen sense of humor and a kindly regard for his fellow men. He was therefore popular in military circles and well known and respected in those parts of the United States in which he served. He was well acquainted in Alaska, having traveled extensively there. His early passing from life cut short a career of much promise.

---

[3] See Official Army Register, January 1, 1940.

Lieutenant-Colonel Atkins was District Commander of the American Legion in Washington, D. C., in 1929–1930, and a member of the Forty and Eight, Torch Club, and Army-Navy Country Club in that city. He was also a member of the Society of American Military Engineers and a Thirty-Second Degree Mason.

On May 10, 1919, he was married to Helen H. Clark in Washington, D. C. He is survived by his widow, his son, Douglas C., and his mother.

Lieutenant-Colonel Atkins was elected a Member of the American Society of Civil Engineers on January 15, 1940.

WILLIAM JAMES BACKES, M. Am. Soc. C. E.[1]

DIED JANUARY 20, 1942

William James Backes was born at Hartford, Conn., on April 29, 1879, the son of Frederick W. and Marie Anna (Schwarz) Backes. He died suddenly in Boston, Mass., on January 20, 1942.

Mr. Backes was educated in the public schools of Hartford, the Cheshire Academy at Cheshire, Conn., and Sheffield Scientific School of Yale University at New Haven, Conn. He was graduated from the latter institution with the degree of Bachelor of Philosophy in 1899. In 1920 he received from the Pennsylvania Military College at Chester, Pa., the honorary degree of Civil Engineer.

After graduation, Mr. Backes went to Mexico in July, 1899, as a leveler on railroad location. Later he was employed as an assistant superintendent of erection. He returned to the United States in December, 1900. From January, 1901, to July, 1903, he was employed as an assistant on the Engineering Corps, and later as a transitman, of the Pennsylvania Railroad Company's Lines West. In July, 1903, he entered the employ of the New York, New Haven and Hartford Railroad Company as a transitman in the Maintenance of Way Department. He resigned in April, 1905, to enter the employ of the New York, Pennsylvania and Long Island Railroad Company as an assistant engineer in charge of all field work for driving tunnels and sinking the central shaft on the Bergen Hill Section of the Pennsylvania tunnels into New York, N. Y. In May, 1906, Mr. Backes was appointed chief engineer of the Central New England Railway Company.

This latter appointment enabled Mr. Backes to display that unusual energy, initiative, foresight, enthusiasm, judgment, and ability that characterized his professional life. Some of the major projects completed under his direction were: The construction at Maybrook, N. Y., of the first gravity switching yard in New England, together with the erection of a modern engine terminal and coal handling and icing station; the double tracking and relocating, with heavy grade revisions, of forty miles of line; the replacing of timber bridges with concrete for permanence and heavier loads; the establishing of new and improved standards of maintenance; and the installation of fifteen miles of what at that time was a novel system of automatic signals for single-track operation, being one of the original installations of its kind.

---

[1] Memoir prepared by Walter D. Warren, *Retired* Div. Engr., New York, New Haven & Hartford R. R. Co., Newton, Mass.

Mr. Backes was promoted to engineer of maintenance of way of the New York, New Haven and Hartford Railroad Company in May, 1913, in charge of maintenance and minor construction. He gave his especial attention to improving the property, to raising the standards of maintenance, to increasing the use of labor-saving and time-saving tools and machines, to increasing the interest, and to encouraging the young engineer to advance to higher and more responsible positions in the department. The energy and enthusiasm to improve the department and its members, as displayed by Mr. Backes, reflected not only to his credit as an achievement, but created an increased efficiency in operation and an esprit de corps that did not previously exist. He was again promoted in November, 1923, to assistant general manager in charge of Maintenance, Electrical, Telegraph, and Signal departments. He resigned in June, 1925, to become associated with the Lundie Engineering Company.

In February, 1926, Mr. Backes returned to railroad service as engineer of maintenance of way for the Boston and Maine Railroad Company. In April, 1927, he was appointed chief engineer, and in May, 1933, his jurisdiction was extended by appointment as chief engineer of the Maine Central Railroad and the Portland Terminal companies. At the time Mr. Backes entered the employ of the Boston and Maine Railroad Company, the management had decided on an extensive program of improved standards of maintenance and the construction of several major improvements. In conducting this program, Mr. Backes displayed his unusual energy and efficiency in the rehabilitation of the railroad and established recognition of credit because of his accomplishments. Some of the projects were: Extensive main-track renewals with heavier rail and the installation of stone ballast; replacing with heavier structures, or strengthening, some 700 bridges; increasing the main-line clearances, involving clearances through the Hoosac Tunnel in Massachusetts; construction of a modern retarder-equipped classification yard at the Boston (Mass.) freight terminal; installation of important interlocking plants, extensive centralized traffic-control installations, remote control and color-light installations, and other extensive signal improvements, some of a pioneer nature; replacing the timber trestle area over the Charles River with heavier and more permanent construction, including the erection of four, two-track bascule bridges at the Boston passenger terminal; and the razing of the old facilities and the construction of the new Boston North Station area, including passenger station with arena above, and connecting hotel and terminal buildings. Mr. Backes' acknowledged achievement in these projects was reflected in his organization and direction of the repair work and early restoration to service of the many lines damaged by the disastrous New England floods of 1927–1936. He was appointed consulting engineering in April, 1936, and held this position until his death on January 20, 1942.

On September 25, 1901, he was married to Elsie Marie Goerz. He is survived by Mrs. Backes; two sons, Edward William Backes, Assoc. M. Am. Soc. C. E., and Frederick William Backes; two daughters, Helen M. (Mrs. Wilbur E. N. Manosh) and Marie Gertrude (Mrs. Duncan E. Littlefair); and two sisters, Mrs. Karl Peiler and Mrs. Helen Stearns.

Mr. Backes was active in the local affairs of the community in which he resided. He was a Mason, maintaining that affiliation until his death. He was a member of the Episcopal Church. He was also a member of the Yale Club of New York City and Boston; Albemarle Country Club at Newton, Mass.; New England Traffic Club; Boston Traffic Golf Club; New York Railroad Club; the New England Railroad Club, which he served as president from 1919 to 1920; and the Yale Engineering Association. In 1908 he became a member of the American Railway Engineering Association and for a number of years served on the Committee on Rail.

He was intensely interested in the railroad world, and gave loyal service to the company with which he was connected. He devoted much time to, and took an active part and interest in, all problems relating to increasing the efficiency, the economy, and the capacity of the existing railroad system. He was distinguished and recognized for his outstanding achievements in railroad maintenance and construction work, and for his ability to pioneer and progress through the force of his energy, ability, and enthusiasm. He was highly regarded by all who knew him, and all recognized his unusual personal integrity, sterling honesty, and fairness, which were so well shown by his record and career.

Mr. Backes was elected a Junior of the American Society of Civil Engineers on May 31, 1904; an Associate Member on July 9, 1906; and a Member on October 1, 1912.

CHARLES JOSEPH BENNETT, M. Am. Soc. C. E.[1]

DIED MARCH 24, 1941

Charles Joseph Bennett was born in Frome, Somerset County, England, on February 9, 1878, the son of William T. and Lydia (Perkins) Bennett.

When he was three years old, his parents came to the United States, and he received his early education in the grammar and high schools of Amsterdam, N. Y. Here he first came in contact with engineering by working as rodman for the city engineer of Amsterdam while still in high school. He continued this work through his college course and for some months thereafter. In 1901 he was graduated from Union College, at Schenectady, N. Y., with the degree of Bachelor of Engineering.

---

[1] Memoir prepared by Robert J. Ross, M. Am. Soc. C. E.

During the early part of 1902 he entered the service of the Metropolitan Street Railway Company in New York, N. Y., serving as an assistant in layout and inspection of construction. He remained on this work until October, 1903, when he went with the New York Central Railroad Company as assistant engineer in elimination of grade crossings at Schenectady.

In March, 1905, he went to Connecticut and became successively transitman and assistant engineer on construction of the freight terminal in Hartford for the New York, New Haven and Hartford Railroad Company. After completion of this work he was appointed division engineer of the same railroad's midland division, which position he retained until September, 1909, when he resigned to become assistant engineer of the Saybrook and Lyme Bridge Commission of Connecticut.

On March 28, 1910, he was appointed deputy superintendent of streets of the City of Hartford, under the late Frederick L. Ford, M. Am. Soc. C. E. He was appointed superintendent on February 10, 1911, and remained until his appointment as Connecticut state highway commissioner on February 26, 1913. During the next ten years Mr. Bennett continued as highway commissioner and under his direction many hundreds of miles of Connecticut highways were constructed. Leaving the Highway Department in 1923, he became general manager of the Edward Balf Company and, later, director of production for the Fuller Brush Company, both of Hartford.

In 1928 he entered private practice as a consultant, and the work of the firm of Bennett and Terry included not only a diversity in type of projects but projects of considerable importance and magnitude. In recent years he had served as consultant for the Hartford Hospital, Trinity College (in Hartford), the Groton-New London Bridge Commission, the Connecticut Highway Department, and other public and private agencies.

At the time of his death Mr. Bennett was acting as executive secretary to the Hartford Flood Commission, a post which he filled most ably, and it is unfortunate that his span of life could not have been extended so that he might see the consummation of this project, to which he had devoted so much time and energy.

Among his other engineering accomplishments and affiliations were membership in the Connecticut Society of Civil Engineers (of which he was a past-president and honorary member), the American Road Builders Association (of which he was a past director), and the American Association of Highway Officials, which he once served as president. He conducted special surveys of the Michigan state highways in 1924 for the Detroit Automobile Club and an investigation of the Street Department of New Rochelle, N. Y., in 1921 for the Chamber of Commerce of that city. He also made a special report on the Merritt Parkway in Connecticut to Governor Wilbur Cross. He acted as manager of the Hartford Community Chest work relief program and at various times lectured on engineering at the University of Michigan, in Ann Arbor; at Yale University, in New Haven, Conn.; and at Columbia University, in New York City.

Two educational institutions conferred honorary degrees on Mr. Bennett. Yale University honored him with the degree of Master of Arts in 1922 and in 1926 his alma mater, Union College, conferred the degree of Master of Science.

Mr. Bennett had a strong sense of duty to the community and served on numerous committees and civic bodies, including the Building Commission of the City of Hartford, the Park Board of the City of Hartford of which he was president for a term, the Regional Planning Commission of the (Hartford) Metropolitan District, and the Board of Trustees of the Connecticut State College (later University of Connecticut) in Storrs. He was appointed by the Governor as delegate to the 1931 National Conference on Home Building and Home Ownership. He was particularly active in work for the colored people in the Hartford tenement district and served as president of the Board of Directors of the North End Federated Clubs, an organization sponsoring work of all kinds among the tenement dwellers. A "fresh-air" camp maintained near Hartford was named "Camp Bennett" in his honor.

Mr. Bennett was a member of St. John's Episcopal Church, in Hartford, and Beta Theta Pi Fraternity. He was a past-president of both the Hartford Rotary Club and the University Club of Hartford.

On August 22, 1905, he was married to Marguerite Balch of Galway, N. Y. He is survived by his wife; two sons, Charles W. and Gordon; and three daughters, Elizabeth J. (Mrs. George A. Wardinski), Alison M. (Mrs. Kingsbury Dyke), and Patricia H. Bennett.

It is seldom that a man is found who can offer such able and diversified assistance to his fellow men and who at the same time is willing to devote such boundless energy to civic and professional activities. Such a man, however, was Charlie Bennett, for whom no eulogy is necessary. His works and deeds speak for themselves. It is particularly fitting that the affection and respect of his fellow men could be exemplified by the beautiful and appropriate funeral services, held in the chapel of Trinity College, in the design and erection of which he rendered able professional assistance. Every station in the community's life was represented. All were there because of a profound sense of loss. The inspiration to be derived by his fellow men from the life of such a citizen, however, can never be lost.

When Yale in 1922 conferred the honorary degree on Mr. Bennett the citation concluded with the following words:

> "Governor Baldwin appointed him State Highway Commissioner which office, fortunately for the State, he still holds. The annual expenditure of public money under his direction is between eight and ten millions. He has built admirable roads under difficult conditions, and is giving the State full value for money expended. He is skillful, shrewd, and honest, and can neither be tempted nor deceived. He is a scientific expert with a Puritan Conscience."

Mr. Bennett was elected a Member of the American Society of Civil Engineers on February 4, 1914.

WILLIAM ALLEN BLAKEMORE, M. Am. Soc. C. E.[1]

DIED NOVEMBER 8, 1941

William Allen Blakemore, the son of Thomas Mark and Jane (Allen) Blakemore, was born on March 2, 1889, at Prairie Grove, Ark. Both the Blakemore and Allen families were planters, descended from English ancestors, who came to the South in Colonial days, and both families contributed soldiers to all of the American wars. His grandfather, John W. Allen, whose slaves built the typical southern colonial home in which Mr. Blakemore was born, came from Virginia to Texas as a young man to fight with Gen. Sam Houston in the Texas War of Independence.

Although the families were all from plantations they believed in education There were college graduates in every generation, many of whom were doctors. Young Allen Blakemore received his preparatory education in the public schools of Prairie Grove. After graduating from the high school, he entered the University of Arkansas, at Fayetteville, where he received the degree of Bachelor of Science in Civil Engineering in 1911.

During the first summer after receiving his degree, Mr. Blakemore, as instrumentman, helped to survey and build the Missouri, Oklahoma and Gulf Railroad from Muskogee, Okla., to Denison, Tex., and then worked in the Maintenance of Way Department after the construction was completed. The following summer, he went to Gary, Ind., as draftsman for the American Bridge Company, where he stayed until the spring of 1913. He then went to Ontario as instrumentman on the construction of the Canadian Pacific Railway. While on this work, a friend wrote him that the United Fruit Company had formed the Trujillo Railroad Company in Honduras, Central America, and engineers were needed to survey a line across the mountains, so he signed up for a year and took charge of locating a part of this difficult line through a wild country.

After a year in the tropics, Mr. Blakemore, in 1915, entered the employ of the Gulf Oil Corporation (then known as Gulf Production Company), in Beaumont, Tex., with which company he spent the remainder of his career with the exception of two years in the armed services of the United States Army during the First World War. His duties consisted in general oil field surveying, retracing old land lines and marking the boundary lines of company leases, staking locations for oil wells to be drilled, locating and constructing pipe lines leading from the oil fields to market, and constructing pump stations, tanks, and other facilities necessary in the development of new oil fields.

In May, 1917, one month after war was declared on Germany, the government called for its first volunteers, and Mr. Blakemore answered the call. He joined the 12th Engineers at Kansas City, Mo., enlisting as a private, and sailed for France a few weeks later. He was promoted to Second Lieutenant while in France and served until the Armistice in railroad construction work immediately back of lines through France, Belgium, and Alsace-Lorraine. Lieutenant Blakemore received his discharge in May, 1919, and returned to the Gulf Oil Corporation in Houston.

---

[1] Memoir prepared by John H. Bringhurst, M. Am. Soc. C. E.

In December, 1919, "Blake," as he was called by all of his friends, was made assistant chief engineer under Frank L. Buford and assumed responsible charge of all surveys for the company. Being a tireless worker himself, he insisted that his men work long hours. Hardships in the field, waist or shoulder deep in oil and mud, meant nothing to him, and he expected his men to follow where he led. The oil field work on the Gulf Coast in Texas, during the "Booms," demanded ingenuity, stamina, and perservance in the surveyor, all of which Mr. Blakemore possessed in a marked degree, and the difficulties of terrain were met and overcome just as Lieutenant Blakemore met and solved his railroad problems under shell fire in France.

In 1931, at the death of Mr. Buford, Mr. Blakemore was made chief engineer, and his direct supervision of work in the field had to give way to his work of more executive nature. Boundary controversies involving enormous sums were frequent. So-called "vacancies" were being claimed and filed in almost every proven oil field. He devoted much of his time to such problems and his skill in directing and interpreting the work of his land survey parties prevented much litigation and won most of the cases that reached the courts.

A friend who was closely associated with him says—

> "I worked with him on a tedious and difficult job in one field where we wallowed daily in the oil covered marsh and slush pits for several weeks in preparing evidence on which a suit involving several million dollars depended. It was settled favorably out of court. I have 'tailed' a surveyor's chain, with 'Blake' on the head end for miles down a county road, with my tongue hanging out in the August heat while the two regular chainmen rested and drove the car. I have worked with him over the scorched prairie grass in another oil field, our lunches tied to our belts but our empty canteens preventing us from eating all day. In over thirty-five years of engineering experience I have worked with no one who had his capacity for hardships and dogged determination to get a job done."

On January 20, 1920, Mr. Blakemore was married at Siloam Sp[illegible], Ark., to Mamie John Brockman, to whom he was engaged before going to France. His first child, Nancy Allen, was born in 1922 and the other, John William, was born in 1930.

His marriage, his devotion to his wife and children, complemented a routine of hard work to which he had given his entire time unstintingly. His innate reserve, his tranquil and unruffled demeanor, which at times concealed from others occasional strong emotions locked within him under perfect self-control, were shed in his home life and, though always gentle and quiet, joy, happiness, and pride in his family radiated from his countenance.

He enjoyed attending all kinds of athletic contests and especially those of his own college. While watching a football game between the University of

Arkansas team and that of Rice Institute, in Houston, with his daughter, a student in the Rice Institute cheering section and his wife and son helping him cheer for Arkansas, Mr. Blakemore suffered a heart attack and was dead upon arrival at the hospital.

Mr. Blakemore was elected a Member of the American Society of Civil Engineers on October 29, 1934.

EDWARD RICHARD CARY, M. Am. Soc. C. E.[1]

Died July 17, 1941

Edward Richard Cary was born in Troy, N. Y., on December 19, 1865, the son of Tallmann and Elizabeth (Lounsbury) Cary. He received his elementary education in the public schools of Troy, and at the Troy High School. Entering Rensselaer Polytechnic Institute, in Troy, in September, 1884, he was graduated with the degree of Civil Engineer in 1888.

In the fall of that year he became a member of the Faculty of Rensselaer Polytechnic Institute as assistant and instructor in the Department of Surveying. Likewise, from 1888 to 1904, he served as registrar of the Institute. In September, 1902, he was appointed assistant professor in the Department of Surveying, and in 1904 he became professor of geodesy, railroad engineering, and highways, in which capacity he served the Institute until his retirement in 1936.

Professor Cary began private practice immediately upon graduation, engaging mainly in surveying and municipal engineering. From 1896 to 1906 he was a member of Cary and Roemer, Civil Engineers. He served as city engineer for Troy from 1900 to 1902, and again from 1906 to 1908. At different periods he was engaged as engineer by near-by municipalities.

He was married on June 21, 1892, to Mary Lyman, who, with a daughter, Helen (Mrs. F. W. Cappelmann), survives him. He is also survived by a sister, Mrs. G. K. Gormly.

Professor Cary was the author of "Slide Rule Solutions of Railroad Problems"; "Geodetic Surveying"; and "Elements of Diagrams." He was a member of the American Railway Association, Sigma Xi, and Tau Beta Pi.

Generations of Rensselaer men will long remember him as a teacher and adviser. Members of the Rensselaer faculty will remember him as a faithful and ever helpful colleague. His professional associates will remember him as a distinguished engineer. All who ever knew him will long remember him as a friend.

Professor Cary was elected a Member of the American Society of Civil Engineers on April 2, 1902.

---

[1] Memoir prepared by H. O. Sharp, M. Am. Soc. C. E., and H. H. Nugent, Prof., Dept. of English, Rensselaer Polytechnic Inst., Troy, N. Y.

FRANK LYNTON CHASE, M. Am. Soc. C. E.[1]

Died April 1, 1941

Frank Lynton Chase, retired vice-president of the Lone Star Gas Company and a pioneer of the natural gas industry, died April 1, 1941, and was buried in the Green Lawn Cemetery at Columbus, Ohio. He died while en route to his home in Dallas, Tex., after a vacation in Florida, during which he suffered a fall.

Mr. Chase was born in Bucyrus, Ohio, on May 23, 1865, the son of Francis and Jenny (Weatherbe) Chase. His father was from a Vermont family which produced many men of note. He was an engineer by profession and at the time of Mr. Chase's birth was chief engineer of the Pittsburgh, Fort Wayne and Chicago Railway Company. He died in Mr. Chase's early childhood. Frank Chase attended Washington and Lee University at Lexington, Va., for two years, and after working several years he entered Massachusetts Institute of Technology, in Boston, Mass., graduating in three years in the class of 1890.

Following his graduation he was for a year a transitman on location for the Union Pacific Railroad Company in the State of Washington. On July 1, 1891, he entered the engineering department of the Cleveland, Cincinnati, Chicago and St. Louis Railway at Indianapolis, Ind., under George W. Kittredge, Hon. M. Am. Soc. C. E. Mr. Kittredge was chief engineer of this road which was newly formed by the consolidation of a number of other lines. After about two years he entered the service of the Baltimore and Ohio Railroad Company and was engaged in grade revision and bridge designing. In 1900 he went to the New York Central and Hudson River Railroad as bridge engineer under William J. Wilgus, Hon. M. Am. Soc. C. E., chief engineer. He had charge of the design and construction of nearly all the bridges on the system—work which was made necessary by the heavier equipment then coming into use. In 1903 he was elected president of the Jamestown, Chautauqua and Lake Erie Railway and the Jamestown and Chautauqua Navigation Company. While in this position he conceived the idea of the practicability of a gasoline-driven railway passenger coach. His experiments were conducted during the development period of the gasoline engine and he secured patents covering his ideas.

His experience in the natural gas business, which became his lifework, began a few years later when he was placed in executive charge of eight companies that served Dayton and Springfield, Ohio, and the towns in the Miami Valley of Ohio. In this capacity he supervised both pipe-line and distribution company activities.

Mr. Chase became associated with the Lone Star Gas Company in 1917 at a time when this company was struggling to obtain sources of supply sufficient to permit its continued operation. His outstanding success in the solution of this problem was largely responsible for the present status of the company. In 1925 he organized and became the president of the Community Natural Gas Company, a Lone Star Gas Company subsidiary. This company was created for the purpose of extending domestic and industrial gas service to a large number of small cities and towns in Texas and Oklahoma located adjacent to the main trunks of the pipe-line system.

---

[1] Memoir prepared by Edward C. Connor, M. Am. Soc. C. E., and Elmer F. Schmidt, Vice-Pres., Lone Star Gas Corp., Dallas, Tex.

Aside from his immediate duties Mr. Chase rendered valuable service to the gas industry as a whole, having served as a director of the former Natural Gas Association of America, as chairman of the Natural Gas Section of the American Gas Association, and as a member of the management committee of the same organization. For many years he was active in the work of every association in the Southwest dealing with natural gas and oil, and he maintained a keen interest in all matters pertaining to engineering advances and conservation measures.

In 1935 Mr. Chase was appointed to the newly formed Federal Commission, designated as the advisory board of the United States Bureau of Mines, which functions as an advisory body to the chief of the bureau and counsels with him on matters of bureau policy.

After twenty-two years of service as an official of the Lone Star Gas Company, Mr. Chase retired in 1939, but he retained offices in the company building and remained active in company affairs in an advisory capacity until his death. As late as May, 1940, he was honored as the "grand old man" of the natural gasoline division of the American Petroleum Exposition at Tulsa, Okla., an award that is an annual feature designed to honor men who have contributed to the progress of the petroleum industry.

Despite the fact that heavy executive responsibilities demanded most of his attention during the period of his association with the natural gas industry, Frank Chase was always an engineer in all that the word implies. Throughout his administrative career he kept the tools of his profession keen and bright—so keen and bright, in fact, that he frequently astonished his younger associates by his unerring approach to the correct solution of complicated technical problems. Above all, however, he was a striking example of what constitutes an educated Christian gentleman. His inquiring mind found interest in the realms of pure science. Lobachevski and Riemann, Michelson and Einstein were his familiars, and he was intrigued by the elusive problems growing out of a consideration of time and space. However, his normal predilection for things scientific did not dull his intelligent appreciation of the fine arts. He was a keen student of philosophy and economics and was an omnivorous reader of the literature of these subjects. However, in the midst of his crowded life he found time to serve as a member of the vestry of his cathedral parish.

He was a man of fine stature, and in his undergraduate days at Washington and Lee was a varsity tackle. His imposing person, coupled with his dominant intellect, made him an outstanding personality in any group. Once he had rationalized his conclusions on any debatable subject he would support these conclusions with vigor; nevertheless, he was tolerant of the opinions of others even if they conflicted with his own. He enjoyed nothing more than a clash of ideas with those whose knowledge of a subject forced him to rally his mental reserves to the attack.

To those who were privileged to know him well, several of his traits of character and accomplishments stand out above the high level of his professional attainments. His keen sense of fairness dominated his dealings with others. He never negotiated a contract without keeping foremost in his mind the question of whether or not its provisions were equitable with respect to the best interests of the other contracting party. This trait found concrete expression in the gas purchase contracts that he negotiated with the natural gas producers in Texas and Oklahoma. To him the current market price of gas was secondary to the question of whether or not gas could be produced profitably at the price agreed upon.

His interest in the advancement of his younger associates extended far beyond the normal relationship between an executive and his subordinates. He delegated responsibilities freely and exacted results with firmness, but he always maintained a sympathetic and fatherly interest in the progress of every individual responsible to him. As a result of this policy, practically all of the operating executives of the Lone Star Gas Company and Community Natural Gas Company, as well as the department heads of the operating sections of these companies, owe their advancement to his personal interest in their respective careers.

Waste and improper utilization, which for so long were the outstanding characteristics of natural gas operations in the Southwest, were abhorrent to him. Almost single handed he led the crusade of conservation against the entrenched forces of self-interest that ultimately resulted in the enactment and enforcement of rational conservation laws that have materially extended the life of natural gas service to the domestic consumers of the Southwest and have made it feasible to extend natural gas service to the large population centers of the Middle West.

He had the profound conviction that a public utility operating in a given territory was obligated to render a complete service to all of that territory without giving primary consideration to the limitations imposed by the prospects for profit that might be involved in any given extension of service. As a result of this conviction, the Community Natural Gas Company was organized and through this agency natural gas service has been provided to more than three hundred small cities and towns variously located in an area of approximately 12,000 sq miles—a program unparalleled in the history of the natural gas industry. Above all, he had an abiding faith in the destiny of Texas, the state of his adoption. Few of its citizens have contributed more to the fulfilment of this destiny than has Frank Chase—engineer.

On November 12, 1895, he was married to Sarah Winchell Forbes, who, with two daughters, Sarah Elizabeth (Mrs. Ralph W. Lee, Jr.) and Priscilla Chase Bergin, survives him.

Mr. Chase was elected an Associate Member of the American Society of Civil Engineers on November 4, 1896, and a Member on November 1, 1899.

EDUARDO JUSTO CHIBÁS, M. Am. Soc. C. E.[1]

DIED AUGUST 22, 1941

Eduardo Justo Chibás was born in Santiago de Cuba, on February 28, 1869, the son of Eduardo Chibás and Mercedes (Guerra) Chibás. He received his early education in his native city, obtaining the degree of Bachelor of Arts from the Santiago de Cuba Provincial Institute.

Cuba was at that time under the Spanish régime; there was no engineering school in the country, and the Santiago de Cuba Province (later Oriente Province) was practically isolated from Habana or the remainder of the island, except by boat. Like many other sons of well-to-do families, young Eduardo Chibás was sent abroad for a professional career. He went to the United States and attended Rensselaer Polytechnic Institute, at Troy, N. Y., where he was graduated with the degree of Civil Engineer in June, 1889. He distinguished himself as a conscientious student and became a member of Sigma Xi, honorary scientific fraternity, whose emblem he carried in his watch chain throughout his life.

After graduation he went back to Cuba and worked for a sugar estate of the Oriente Province. The internal unrest of the country, preliminary to its last and successful struggle for independence, already was felt, and there were few or no prospects for engineering activities. He went back to the United States and served as assistant engineer for the Duquesne Traction Company and for the Pittsburg, Allegheny and Manchester Electric Railways, at Pittsburgh, Pa.

Mr. Chibás was very much interested in mining, probably on account of the abundance of ore deposits in his native province of Cuba, and he examined and reported on deposits of manganese, iron, and gold, and also on other developments, in Cuba, Panama, Colombia, and Venezuela for several American and English concerns. He was in actual charge of developing some of these mines, built railroads through mountainous country, and made extensive surveys.

Then in 1898 came the Spanish-American War, and he had the opportunity to contribute in an active way to the liberation of his country from the secular Spanish dominion. He joined the United States Fifth Army Corps as assistant civil engineer under the late Brig. Gen. William Ludlow,[2] M. Am. Soc. C. E., chief engineer of the Army, and later under Col. George McC. Derby, M. Am. Soc. C. E. He had charge of reconnaissance around the San Juan and Caney forts and the City of Santiago, locating trenches and positions of the different regiments before and after the capture of those forts, until the surrender of the City of Santiago. The official maps of the Santiago campaign bear his signature with those of the officers of the U. S. Engineer Corps. It is said that in connection with his reconnoitering duties he made use of a military balloon, an unusual feature at that time in the western hemisphere, and also, that while engaged in his engineering work he took the first prisoners of the war.

---

[1] Memoir prepared by Francisco J. Gastón, M. Am. Soc. C. E.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. LXXXV (1922), p. 1700.

Back in civil life and enjoying the invigorating air of his country's political freedom, he devoted himself to the development of the natural resources of his native Province. In January, 1899, he was appointed chief engineer and general manager of the Guantánamo Railroad Company. While with this company, he organized the Guantánamo Ice Company, of which he became president, and he held that position until 1924.

In 1902, at the time of the inauguration of the Republic of Cuba, he moved to Santiago where he acted as a promoter and practiced as a consulting engineer and contractor. Enjoying great personal prestige, because of his honesty, engineering capacity, and unusual business insight, he organized different companies and built a large number of engineering works.

He prepared plans for an electric light and power plant for Santiago and organized the Santiago Electric Company, which built the plant. Later, he made plans for the electric tramways of the city, obtained the necessary concessions, and reorganized the company under the name of the "Santiago Electric Light and Traction Company," which built and inaugurated the system in 1908. He was with this company as a member of its Board of Directors and as consulting engineer until 1921. These and other enterprises, such as the Vista Alegre Development, changed the physical aspect of his native city, Santiago de Cuba, from a sleepy colonial town to a thriving, prosperous community.

In 1906 Mr. Chibás organized the Guantánamo Electric Company, becoming its president, and built the electric plant. Later, in 1916, he reorganized the company and built a hydroelectric plant at the Guaso River, 14 miles from the city, with a head greater than 600 ft and about 1,000 hp. He served as president of this company until 1924.

In January, 1911, at the time of a water famine in Santiago de Cuba that threatened to stop all industrial activities in the city, he suggested that tubular wells be driven to an underground reservoir in San Juan Valley. Once this was authorized, he proceeded with the work and in two weeks obtained water in sufficient quantity to relieve the situation. He then built an emergency system of water supply for the city. When there is a shortage of water from other sources, the San Juan wells can still be counted on for their share of good underground water.

From 1912 to 1920 he was vice-president of the Santiago Brewing Company, of New York, N. Y., and Santiago de Cuba, originators of the "Hatuey" beer, later owned by the Bacardí Company. He was also vice-president of the Compañía Azucarera Oriente (from 1914 to 1921), which developed a new sugar state, later known as "Altagracia," in Oriente Province.

In 1922 Mr. Chibás changed his residence to Habana and, after he had disposed of most of his property and business interests in Oriente Province, he found himself in a very sound economical position. He invested in real estate and built the "Chibás Building," one of the first large apartment houses in the City of Habana.

Although not giving up engineering, and studying especially the water supply problems of Santiago de Cuba and Habana and devoting much of his time to the Cuban Society of Engineers, he contributed largely and generously to civic activities. He was a member and at one time the president of the Rotary Club of Habana, a member and president of the League Against Cancer, a member and president of the Real Estate Center of Habana, and a member and president of the National Association of Charities. His coöperation was solicited by numerous clubs and societies, and he belonged to the Habana Yacht Club, the Country Club, the Automobile Club, Pro-Arte Musical, etc. He was a member of the Institute of Mining and Metallurgical Engineers, and one of the founders and first president of the local section of the American Water Works Association, which is said to be the only branch of the Association outside of the United States. He joined the Sociedad Cubana de Ingenieros when this was founded in 1908, and acted as its delegate in Santiago for many years. He was elected president of the Society for the term 1930–1932 and was reelected for 1932–1934.

His idea of fulfilling civic duties led him into politics; although refusing to join any of the conventional political parties, he was staunch in the big national issues. During the second term of President Gerardo Machado, Mr. Chibás' elder son, Eduardo, was actively engaged in oppositional activities, which at that time could not be other than of a revolutionary character. Government agents denounced and involved Mr. Chibás, the father, and he was imprisoned and court-martialed under most absurd charges, from which, of course, he was in due time wholly exonerated. Mr. Chibás was at that time president of the Cuban Society of Engineers, and many of its members felt it a duty to attend the sessions, some of them as witnesses for the defendant. To show how engineers stood by Mr. Chibás, it may be mentioned that he was reelected president of the Society while he was in prison. During all the long and cruel process, Mr. Chibás maintained a perfect dignity. It was easily observed that most of the members of the military board, although demanding the highest penalty for the accused, were impressed by his fine character. One of the sergeants attending the sessions and acting as a stenographer was no other than Fulgencio Batista, later President of the Republic.

After the revolution that put an end to the Machado Government, Mr. Chibás was appointed Secretary of Public Works by President Carlos Manuel de Céspedes during his short term. Later, he was repeatedly asked to occupy the same or another important government position, but he sternly refused. He served, however, as president or member of many official or private commissions of a technical, economic, or social character.

Mr. Chibás was the president of the local section of the Rensselaer Polytechnic Institute Alumni Association. In 1939 he was elected president of the national association, which was considered a great honor, because never before had a foreigner and nonresident been elected president of any of the alumni associations of the great universities of the United States. This coincided with the fiftieth anniversary of his professional life, and it was the occasion for a homage to Mr. Chibás from his fellow engineers of the Cuban Society of Engineers. A bronze plaque was then presented to him as a token of appreciation.

In February of the same year, the Rensselaer Polytechnic Institute Alumni Association, under the presidency of Mr. Chibás, celebrated its annual reunion in Habana. William Otis Hotchkiss, M. Am. Soc. C. E., president of the Institute, and a host of professors and distinguished engineers assisted; the entire gathering was pronounced a great success. At the reception for the visitors at the Cuban Society of Engineers, the president of that society referred to the special honor bestowed on Mr. Chibás by the Rensselaer men, and this token of affection rendered to a Cuban, he said, "went deeply into our hearts"; and he added, addressing the visitors:

> "Chibás is now your President, but he is none the less our Chibás, a member of this Society who was elected and reelected its President, one whom as an engineer and a public citizen, we all love and respect. In this way a sort of spiritual relationship has been established between the Rensselaer Polytechnic Institute and the Cuban Society of Engineers."

A good example, it might be added, of the "Good Neighbor" policy.

Rensselaer Polytechnic Institute conferred the degree of "Doctor of Engineering," *Honoris Causa,* on Mr. Chibás in 1940. He is mentioned in "Who's Who in Engineering" for 1941.

He published a number of pamphlets and reports on many of his engineering activities and on economical subjects. He was a member of the commissions that reported on the water supply problems of Santiago de Cuba and on the 1932 earthquake in the same city. These latter reports were published in *Revista de la Sociedad Cubana de Ingenieros.*

Mr. Chibás, although of an energetic nature, was above all a kind man. He was always willing to help, and received with a smile and listened to all. It can be stated truly that he made personal friends of all who had occasion to meet him. His outstanding qualities were personal honesty and kindness, engineering and business ability, and civic spirit.

On November 11, 1906, he was married to Gloria Ribas, at Camagüey, Cuba. They had two sons, Eduardo and Raul. Mrs. Chibás died, and on February 1, 1933, he was married to Conchita Ribas Agramonte, of Washington, D. C., who together with the two sons by his first marriage, survives him. His brother, Luis F. Chibás, a mining engineer of good standing, also survives him.

Mr. Chibás was elected a Junior of the American Society of Civil Engineers on March 31, 1891; an Associate Member on May 6, 1896; and a Member on January 3, 1900. He had been enjoying life membership since 1931.

WILLIAM TURLEY COBURN, M. Am. Soc. C. E.[1]

Died January 24, 1941

William Turley Coburn was born in Washington, D. C., on May 30, 1885, the son of Jennie and Turley Coburn of French Huguenot and Irish ancestry.

---

[1] Memoir prepared by Lester C. Hammond, M. Am. Soc. C. E.

His engineering training was obtained at the University of Maryland, at College Park, and at George Washington University, at Washington, D. C.

His early work to 1913 was with the office of the engineer of bridges in Washington, D. C. From 1913 to September, 1918, when he joined the United States Army, he was connected with several important engineering projects. He worked during these years with Parsons, Klapp, Brinckerhoff and Douglas, of New York, N. Y., as cost engineer on the Salmon River (N. Y.) power development and inspector of dredging for the Cape Cod Canal in Massachusetts; with Jarrett and Chambers Company, Inc., of New York City as office manager of the Bear Lake power development in Idaho; and with the Foundation Company of New York City as engineer assistant to the superintendent and office manager on the power plant at Logan, W. Va., and on the construction of several industrial plants in New York, Pennsylvania, Virginia, and Ohio.

His engineering career was interrupted by his enlistment in the Army in the fall of 1918. He was appointed to the Quartermaster Corps and ordered to France, in October, 1918, as casual officer, to rebuild roads at the front. On his way there the Armistice was signed and he was returned and assigned as executive officer at Pontanezen Barracks, Brest, France, under Gen. Smedley Butler, U. S. Marine Corps. He remained on the construction work of enlarging the camp, which was used for the debarkation of troops to the United States after the Armistice, until he became ill with Spanish influenza the following spring. He was returned in the hospital ship *Leviathan* on April 2, 1919, and was sent to the Walter Reed Hospital. He was discharged from the service on April 27, 1919. He continued his Army affiliations in the Reserve Officers Training Corps and was appointed First Lieutenant. During his services in Detroit, Mich., with the 310th Engineers, he became a Captain. Further promotion would have been given him for his conscientious and valuable service had not his engineering work in many parts of the country prevented more active duty in the Reserve Corps.

His positions after his discharge from the Army included auditor and accountant on engineering reports and income tax with the Internal Revenue Bureau, at Washington, D. C., and six years as assistant manager with Parklap Inc., of Detroit, on construction of large reinforced warehouses and refrigeration plants in Detroit; Albany, N. Y.; Buffalo, N. Y.; Toronto, Ontario, Canada; and Montreal, Quebec, Canada.

His later work as utility officer of the Veterans Administration continued until his death. On April 1, 1931, he was appointed to the Veterans Administration Facility at Lincoln, Nebr.; from there he was sent to Helena, Mont.; and on July 13, 1939, he was promoted to grade Professional 5 and transferred to Danville, Ill. The Veterans Administration operates ninety-one field stations, which include hospital facilities. The utility officer is in charge, under the manager, of maintenance of physical plant and equipment and the operation of mechanical and non-medical facilities, including power plant, laundry, farm, motor vehicles, police and fire protection, and building equipment. It naturally follows that utility officers must possess professional and administrative ability to a large degree. L. H. Tripp, director of construction of the Veterans Administration, pays this tribute to Captain Coburn:

> "Because of Captain Coburn's very high qualifications, he was sent to Danville which is the second largest mental hospital under the control of the Veterans Administration, having a capacity of approximately 1900 beds. Captain Coburn's service there was highly successful and several practices which he initiated have become standard throughout the Field service. Due to his qualities of cooperativeness, courtesy and sympathy, he was highly successful in the utilization of patient labor, and constructed several fine service buildings such as shops and laundry very largely through the use of patient labor. Captain Coburn enjoyed the unqualified esteem, respect and affection of every one who came in contact with him."

Dr. George A. Rowland, the manager of the Danville Facility, stated in his last official communication referring to Captain Coburn:

> "Captain Coburn's death came as a shock to me. I thought a great deal of him, and soon learned to depend on his judgment. He was a gentleman in every respect and a fine and efficient Utility Officer. We will all miss him greatly."

Captain Coburn enjoyed people and had an unusual talent for friendly association with them in business and social life. He was a member of Sigma Alpha Epsilon fraternity, a Thirty-Second Degree Mason, and a Shriner. One of his keen interests during his Army career was his membership in the Sojourners.

He was married in Baltimore, Md., on August 9, 1918, to Blanche E. Wilmot, who survives him.

The funeral services were held in the Veterans Administration Chapel at Danville and at Fort Meyer Chapel, Virginia. Interment was at Arlington National Cemetery in Virginia.

Captain Coburn was elected an Associate Member of the American Society of Civil Engineers on May 28, 1923, and a Member on January 13, 1941.

EMMETT FILMORE COLLINS, M. Am. Soc. C. E.[1]

DIED MAY 8, 1942

Emmett Filmore Collins, the son of Richard M. and Frances M. (Lybrook) Collins, was born at North Judson, Starke County, Ind., on January 5, 1873. He received his education at Purdue University, in Lafayette, Ind., and was graduated with the degree of Bachelor of Science in Civil Engineering in 1894.

His professional career began immediately after graduation, and from 1894 to 1898 he held various positions as rodman, instrumentman, and draftsman. Beginning with his work as chief engineer of the Escanaba and Lake Superior Railroad Company in June, 1898, he thereafter held responsible positions in the location and construction of important railways, which led him into various sections of the United States and Canada. These engagements covered work on many important railway systems, such as the Chicago and North Western; Chicago, Milwaukee and Puget Sound; Wabash; Kansas, Oklahoma and Gulf; and the St. Louis-San Francisco.

---

[1] Memoir prepared by Frank G. Jonah, Hon. M. Am. Soc. C. E.

Mr. Collins was resident engineer in Oklahoma from 1901 to 1902 on construction of lines which later formed part of the "Frisco System." He held the same position in Texas from 1904 to 1905 on what was then known as The St. Louis, Brownsville and Mexico Railway. After that he had some engagements in West Virginia, and in 1910 was engaged in making surveys and estimates for various railway projects in the Southwest. His work on these various railways was at a time when they were engaged in extensive developments in new territory in the Southwest and Northwest, and this gave him a very diversified and practical experience.

He returned to the "Frisco" in August, 1912, and was with that company continuously until 1920. During this time he acted as principal assistant engineer, valuation engineer, and chairman of the Valuation Committee on Federal Valuations. He retired from the "Frisco" in 1920 to devote himself to his private business, but during his retirement he had many engagements as consulting engineer on appraisals and valuations.

Mr. Collins' work was always characterized by accuracy and good judgment. He was a gentleman of very likable personality and made many lasting friendships.

He was married in St. Louis, Mo., on June 4, 1919, to Genevieve A. Purcell, who, with one daughter, Jean Elizabeth, survives him.

Mr. Collins was elected a Member of the American Society of Civil Engineers on December 3, 1913.

CHARLES STRATTON DAVIS, M. Am. Soc. C. E.[1]

DIED JANUARY 2, 1942

Born near Oxford, N. Y., on November 16, 1866, Charles Stratton Davis was the son of John Perkins Davis and Almeda (Buckley) Davis. He attended the local district school and Oxford Academy, from which he was graduated in 1885. He then entered the College of Civil Engineering of Cornell University at Ithaca, N. Y., from which he was graduated in 1889 with the degree of Civil Engineer. He was vice-president of his class during his sophomore year and was a charter member of Phi Gamma Delta fraternity.

In 1889 he was employed by the Massillon Bridge Company at Massillon, Ohio, and in 1893 became chief engineer. He was then transferred to the headquarters of the company at Toledo, Ohio, where he had charge of designing, estimating, and erecting, both in connection with the construction of new bridges and the rebuilding of old bridges. Under his direction the Massillon Bridge Company repaired and reinforced the Eads' Bridge over the

---

[1] Memoir prepared by Daniel E. Davis, M. Am. Soc. C. E.

Mississippi River at St. Louis, Mo. Today this bridge is carrying the heaviest locomotives in use.

In 1907 Mr. Davis entered private practice in Toledo. During this time he prepared stress sheets and working drawings for standard plate girder bridges for several railroads in Brazil and Mexico. He also examined, repaired, and built bridges for the Chicago and Eastern Illinois Railroad Company, the Cincinnati, Hamilton, and Dayton Railroad Company, the Pennsylvania Railroad Company, and for the City of Toledo.

In 1914 he was appointed senior structural engineer in charge of the Bridge Branch, Southern District, Interstate Commerce Commission, with headquarters at Chattanooga, Tenn. He continued in this work until 1919, except for an interval of two years when he served as structural engineer with the Pennsylvania-Detroit Railroad Company.

In 1919 Mr. Davis entered private practice in Pittsburgh, Pa. His first work was the engineering and construction of the Washington Crossing Bridge, a concrete arch bridge over the Allegheny River at Pittsburgh. Among his clients were the City of Pittsburgh, the Pittsburgh and West Virginia Railway Company, the Pittsburgh Railways Company, and the Carnegie Institute in Pittsburgh.

Mr. Davis leaves his wife, Grace Gilbert Davis; a daughter, Charlotte Marie, of Hampton Hall, Pittsburgh; and a sister, Mrs. Sackett H. Mead, of Oxford, N. Y.

Mr. Davis held a commission as Lieutenant Colonel, Engineer Reserve. He was a member of the Engineers Society of Western Pennsylvania, American Society of Military Engineers, and American Railway Engineering Association.

Mr. Davis was elected a Member of the American Society of Civil Engineers on February 1, 1905, and became a Life Member in 1937. He took an active part in Society matters, and a committee of which he was chairman presented a report[2] on sand and aggregate specifications which became a model.

CHARLES YOUNG DIXON, M. Am. Soc. C. E.[1]

Died February 18, 1938

Charles Young Dixon was born on a farm located about three miles west of Niles, Mich., on May 20, 1864. He was the son of James Dixon and Louisa (Young) Dixon, and the third son of five children.

Mr. Dixon attended the public schools at Niles, and among his schoolmates were Ring Lardner, the humorist; and John F. and Horace E. Dodge, later of the firm of Dodge Brothers. For three years he and Horace Dodge were seat mates. He was graduated from the Niles High School in 1882, and from the Ann Arbor (Mich.) High School in 1883. From 1883 to 1887 he pursued the prescribed course in Civil Engineering at the University of Michigan, at Ann Arbor, and in 1887 was graduated from the Literary Department with the degree of Bachelor of Science in Civil Engineering. The Engineering Department had not yet been established.

---

[2] "Specifications for Concrete with Local Aggregates"—Engrs. Soc. Western Pa.—adopted May 3, 1927.

[1] Memoir prepared by George H. Fenkell, Hon. M. Am. Soc. C. E., and Maj.-Gen. (*Retired*) E. M. Markham, M. Am. Soc. C. E.

During the period from 1888 to 1891 Mr. Dixon was engaged on railway and land surveys. In 1892 he entered the employ of the federal government, in the Corps of Engineers, as an inspector. He was promoted to assistant engineer the following year, classified by Executive Order in 1896, promoted to engineer in 1926, continued in service by the authority of the President in 1934, and again in 1935, and retired in 1936. From 1892 to 1895 he was employed continuously on the improvement of the channel through the St. Marys River, in Michigan, and thereafter he was primarily engaged with improvements of the channels between Lake Huron and Lake Erie, and was in direct charge of the construction of the Livingston Channel.

It may be noticed that Mr. Dixon's duties, during the uncommonly extensive period of his public service, were related all but exclusively to the federal navigational improvements at the western end of Lake Erie, the Detroit River, Lake St. Clair, the St. Clair River, Lake Huron, the St. Marys River, and its enlargements into Lake Superior. As a consequence of Mr. Dixon's peculiar engineering capabilities, and his utmost devotion to his tasks, he acquired invaluable knowledge in public interest, which might appropriately be assessed at very high levels, as to national worth.

It is a matter of gratification, combined with affectionate recollections of intimate, official, and personal associations, to make special mention of the most amiable qualities of one who served the Corps of Engineers, U. S. Army, with such loyalty, efficiency, and fidelity, throughout his service in all engineering grades from inspector to the highest position in the Corps—that of principal assistant engineer.

In 1894 Mr. Dixon was married to Mary McIntosh. Mrs. Dixon passed away in 1922. Their children, Donald and Louise, and two granddaughters, survive him. In 1926 he was married to Ella Taylor, who survived him. A sister, Mrs. Hattie Post, and two brothers, Oscar and Wallace, also survive.

Mr. Dixon was known to his acquaintances as somewhat reserved and retiring, but thoroughly kind and considerate. His family and home came first. He was a Deacon in the Congregational Church, and a member of the Masonic fraternity, having been active in lodge affairs in both Ontario, Canada, and Detroit, and a long-time member of the Detroit (Mich.) Commandery No. 1, Knights Templar.

The ending of Mr. Dixon's life, and the completion of his remarkable services to the Corps of Engineers, give proper occasion to memorialize him in this simple and brief fashion, as an outstanding public servant, and a real contributor to the national welfare. Upon his retirement in 1936, his many friends tendered him a testimonial dinner at the Detroit Yacht Club.

Mr. Dixon served as President of the Detroit Engineering Society in 1918 and as President of the Detroit (later Michigan) Section of the Society in 1922–1923.

Mr. Dixon was elected a Member of the American Society of Civil Engineers on November 4, 1903.

WALTER JULES DOUGLAS, M. Am. Soc. C. E.[1]

DIED JULY 2, 1941

Walter Jules Douglas, son of August and Mary Virginia (Crawford) Douglas, was born on October 26, 1872, at Baltimore, Md.

August Douglas, although of English and Scottish descent, was born in Luxembourg. He came to America from France in 1852 and established an importing business in Baltimore. He was married there to Mary Virginia Crawford, a native of Baltimore, whose parents had come to America from Belfast, Ireland. The family moved from Baltimore to Washington, D. C., in 1876.

Walter J. Douglas received his early education in the public schools of Washington and was graduated from the scientific department of the high school. He then attended the Bethlehem Preparatory School for Engineers, in Bethlehem, Pa., from which he was graduated in 1890. Later, he served for ten years as trustee of this school. Immediately after graduation he entered Lehigh University, in Bethlehem, and in 1894 was graduated with the degree of Bachelor of Science in Civil Engineering. These years at Lehigh brought him in close touch with the late Prof. Mansfield Merriman,[2] M. Am. Soc. C. E., resulting in a lifetime friendship and a later professional association.

After graduating from Lehigh, Mr. Douglas started his engineering career as a draftsman with the Coxe Iron Manufacturing Company at Drifton, Pa., which was engaged in the manufacture of engines, pumps, and miscellaneous equipment for coal mines. His work also included the study of coal-breaker construction and the testing of anthracite coals.

In 1895 Mr. Douglas entered the employ of the Lehigh Valley Coal Company, and remained with it until 1897 in the capacity of transitman and assistant engineer. His duties included taking charge of Hazleton Mine No. 1, and its adjacent coal strippings, and the handwork strippings of the Jaensville mines. He participated in all classes of engineering work usual in coal mining, such as the construction of trestles, boilerhouses, mine railways, hoists, shafts, slopes, and tunnels.

During part of the year 1898, he was associated with F. C. Dinney and Company as engineer-in-charge at the Winterpock mine, Chesterfield coal basin, in Virginia, where he made surveys and plans for the development of the mine and of 18 miles of railroad.

---

[1] Memoir prepared by H. Alden Foster and Eugene E. Halmos, Members, Am. Soc. C. E.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 89 (1926), p. 1658.

His activities as a mining engineer ended in 1898, when he was appointed assistant engineer of bridges in the office of the engineer commissioner of the District of Columbia, where he remained about eleven years. In 1901 he was appointed engineer of bridges in the same office, and until he resigned from the position in 1909 he was in charge of the design and supervision of all bridges constructed in the District of Columbia under the general direction of the U. S. Engineer Corps. His duties also included bridge and highway repair and construction, blasting work, preparation of regulations for the storage and use of explosives, and the design of a public bathing beach and floating bath.

At this time, the commissioners of the District of Columbia were planning an extensive bridge-construction program. As preparation for this work, Mr. Douglas obtained a leave of absence during the summer of 1904, and spent about four months in Europe, traveling through France, Italy, Germany, Belgium, and Holland. In each of these countries he studied the notable bridges and conferred with the leading engineers and bridge builders. This experience was of great value in the bridge-design program in which he engaged immediately after his return to Washington.

Of the several bridges constructed in Washington during the period when Mr. Douglas was engineer of bridges, the largest and best known is the Connecticut Avenue Bridge across Rock Creek (later called the "Taft Bridge"), which was completed in 1906. At the time of its construction, it was the largest concrete bridge in the United States, comprising five semicircular concrete arches of 150-ft span, with two concrete approaches each containing an 82-ft arch span. A distinctive feature of this bridge was the use of precast concrete blocks and monolithic unreinforced concrete for construction of the arches. The original design for the bridge was prepared by the late George S. Morison,[3] Past-President, Am. Soc. C. E., having been submitted in a prize competition in 1897. The preparation of the final plans, and the construction of the bridge, however, were under the direct supervision of Mr. Douglas.

Among other bridges which he designed and the construction of which he supervised during this period were the Anacostia Bridge, the Piney Branch concrete bridge, and, in Rock Creek Park, a three-hinged concrete arch and four small concrete bridges distinguished for their rustic charm. The Anacostia Bridge, which crosses the eastern branch of the Potomac River, consists of six three hinged steel arch spans, and a double-leaf bascule span. The Piney Creek Bridge was of particular interest at the time of its construction because it comprised a 125-ft unreinforced concrete arch of parabolic shape, the first arch of this form constructed in America. Mr. Douglas also designed at this time the Edmonson Avenue Bridge and the Wyman Park Bridge, both in Baltimore.

As a result of the prominence he attained through his work in Washington, Mr. Douglas received an invitation to serve as consultant to Barclay Parsons and Klapp, Consulting Engineers of New York, N. Y., on the design of the

---

[3] For memoir, see *Transactions*, Am. Soc. C. E., Vol. LIV, June, 1905, p. 513.

Almendares Bridge at Habana, Cuba. This bridge, containing four unreinforced concrete arches (one of 190-ft span and three of 102-ft span), was supported on pile foundations. The unbalanced horizontal thrusts on the intermediate piers were taken care of by horizontal struts connecting the pile caps below the river bottom. The long-span arch was constructed with three hinges, which were grouted in after completion of the structure. A paper describing the Almendares Bridge,[4] written jointly by Mr. Douglas and Eugene Klapp, was awarded the Thomas Fitch Rowland prize in 1912.

In 1909 Mr. Douglas left Washington to become associated with the late William Barclay Parsons,[5] Hon. M. Am. Soc. C. E., Mr. Klapp and Henry M. Brinckerhoff, M. Am. Soc. C. E., operating under the firm name of Barclay Parsons and Klapp, with offices in New York City, and took charge of all the structural design work of the firm. Among the earlier projects in the design of which he participated were three reinforced-concrete piers for the harbor of Habana and two hydroelectric developments in New York State—the Mohawk Development near Ephratah and the Salmon River Development near Altmar. After completion of the first of these projects he served as President of the Mohawk Hydro-Electric Corporation.

In 1911 he designed and supervised the construction of a railroad car manufacturing plant for the National Steel Car Company at Hamilton, Ontario, Canada, and in 1928 he redesigned and rebuilt this plant, providing additional facilities for the fabrication of automobile chassis and bodies. In 1918 he constructed a similar plant for the Magor Car Company at Passaic, N. J.

From 1915 to 1917 he served as deputy chief engineer of the Cape Cod Canal Company, of which Mr. Parsons was chief engineer. Mr. Douglas took an active part in solving construction problems that developed after the canal was placed in service.

During the early months of the first World War, Mr. Douglas participated in the organization of three plants for the manufacture of ferro-silicon, an essential material for armament manufacture. These plants were located at Niagara Falls, Plattsburg, and Fort Plain, N. Y. In June, 1918, he went to Panama as engineer of maintenance of the Panama Canal, relieving the late Maj. (later General) Jay J. Morrow,[6] M. Am. Soc. C. E., of the Engineer Corps, who was assigned to active duty in France. Mr. Douglas remained in Panama until May, 1919, and during a part of this period, in the absence of the Governor of the Canal Zone, he became Acting Governor, ex officio. During this period he was also vice-president of the Panama Steamship Line and the Panama Railroad Company.

On his return from Panama in 1919, Mr. Douglas renewed his association with Mr. Parsons, becoming a member of the firm of Parsons, Klapp, Brinckerhoff and Douglas. Shortly afterward, the firm was engaged to prepare the detail drawings and to supervise construction of the Sherman Island Dam and Power House, for which the late H. de B. Parsons,[7] M. Am. Soc. C. E., was consulting engineer. The Sherman Island Development, located on the Hudson River above Glens Falls, N. Y., is unique in that it includes a multiple-arch reinforced-concrete dam, 80 ft high (which is founded for the greater part of its length on a sand stratum), and a 50,000-hp power house, also founded on sand.

[7] For memoir, *ibid.*, Vol. 101 (1936), p. 1617.

Between 1925 and 1930, the firm was active in various construction enterprises in Florida. Mr. Douglas participated in the design of many of these projects, including Bayborough Harbor, the Recreation Pier at St. Petersburg, a yacht basin for the Vinoy Park Hotel, and the Tampa Union Terminal.

Between 1925 and 1932, Mr. Douglas served as consulting engineer to the Arlington Memorial Bridge Commission, in connection with the design and construction of the Arlington Memorial Bridge over the Potomac River at Washington, D. C. This monumental structure consists of six reinforced-concrete arches, with maximum spans of 180 ft, and a steel double-leaf bascule bridge of 184-ft span. The project also includes a water gate and river wall along the left bank of the river, and elaborate retaining walls and other monumental structures adjacent to the entrance of the Arlington Cemetery. The design of these structures involved an appreciation of permanence exceeding that normally assigned to engineering structures.

Between 1929 and 1931, Mr. Douglas participated in the design and supervision of construction of the water power plant on the Sacandaga River at Conklingville, N. Y.; the reconstruction and extension of the Spier Falls Plant on the Hudson River; and in the design and construction of the Detroit-Windsor Vehicular Tunnel between Michigan and Ontario, Canada. During the period 1930-1932, as consulting engineer, he supervised the design and construction of a double-lane vehicular tunnel and the design of a pedestrian tunnel, both under the Scheldt River at Antwerp, Belgium. In recognition of his services on this project, he was made a Commander of the Order of the Crown of Belgium.

In 1936 Mr. Douglas served as chairman of the Board of Consultants appointed by the President of the United States to prepare an economic survey for the Atlantic-Gulf Ship Canal across Florida. About this time he also served on a Board of Consultants for the U. S. Engineers in connection with the proposed Passamaquoddy Tidal Power Project in Maine.

Between 1936 and 1938, Mr. Douglas served on the Board of Consultants for foundations and structures at the New York World's Fair. From 1936 to 1940 he was a member of the Board of Consultants to the U. S. Engineers for the design and construction of the Santa Ana, San Gabriel, and Los Angeles (Calif.) flood control projects. During this period he advised the Work Projects Administration (WPA) in New York City on foundation problems at La Guardia Airport, and on other engineering projects in the New York City area. He was also consultant to the commissioner of works of the Borough of Manhattan in connection with the East River Drive.

Among various projects in the design and construction of which Mr. Douglas participated between 1934 and 1940 were the railroad lift bridge over the Cape Cod Canal, the Jamestown Bridge over Narragansett Bay in Rhode

Island, and the Pennsylvania Avenue Bridge over the Anacostia River at Washington, D. C.

Following the 1929 depression, with the subsequent decline of private engineering practice and the increased activities of federal and quasi-federal agencies in the engineering field, Mr. Douglas realized that it would be desirable to have a geographically dispersed practice upon which economic conditions in the United States would have a minimum effect. He accordingly spent several months making investigations and studies of conditions in foreign countries. As a result of these investigations, his firm decided to open an office in Venezuela. This office was opened in Caracas in May, 1938, and was subsequently active on projects for flood control, port development, irrigation, bridges, water supply, and sewage disposal.

While he was engineer of bridges of the District of Columbia, Mr. Douglas already was recognized as one of the most distinguished designers of masonry bridges in America. In consequence, he was honored in 1909 by Professor Merriman, who asked him to be one of the associate editors of the first edition of the *American Civil Engineers' Pocket Book,* published in 1911. Mr. Douglas prepared the section of this handbook on "Masonry and Timber Structures." For the fifth edition (1930), under the editorship of Thomas H. Wiggin and the late Thaddeus Merriman, Members, Am. Soc. C. E., he prepared three sections—"Foundations and Earthwork," "Timber Structures," and "Masonry Structures."

In addition to the aforementioned paper on the Almendares Bridge, he participated in the discussion of various papers published by the Society. He also wrote numerous articles for the technical press. In 1910 he wrote a manual on reinforced concrete which, in that field, was quite similar to present structural steel handbooks.

Although Mr. Douglas never held office in the Society, he frequently assisted in the work of the Committee on Publications. He was also secretary for several years of the Committee on Bearing Value of Soils for Foundations.

Mr. Douglas had a remarkable personality. He was of less than medium stature, slightly built, modest in manners, and quietly spoken. Nevertheless, both in social and professional intercourse, he was soon recognized by people with whom he came in contact as a great man and an engineer of outstanding ability.

His extensive travels, his wide acquaintance with people in all grades of society, his unfailing humor, and his love of literature and the arts made Mr. Douglas an exceptionally versatile conversationalist. There were few topics on which he could not contribute valuable and pertinent comments. He was much interested in the modern trend of social philosophy and liked to discuss current events, both domestic and international, in the light of his broad knowledge of their historical background.

Professionally, Mr. Douglas had an excellent theoretical foundation, which he acquired in college and subsequently through constant study of the progress of engineering science. He was particularly interested in the development of structural mechanics, and in the chemical and physical composition and behavior of building materials and soils.

He had exceptional ability to apply to the design of engineering structures the knowledge of practical considerations derived from his wide experience in actual construction. He knew thoroughly the costs of all types of work, the operating possibilities of building machinery, and the methods best adapted to a particular construction problem.

From the beginning of his active engineering work, Mr. Douglas kept in close touch with his office associates and the men in the field. He was thoroughly human, took extensive interest in the welfare of all persons under his control, and thus was able to build up a following of loyal men who were ready to join him in the various organizations he set up for conducting the diversified work of the firm. His close association with the workers on the job also gave him a keen appreciation of human nature that was outstanding throughout his career.

Walter J. Douglas was gifted with a keen business sense, which was chiefly responsible for the successes his firm achieved during the difficult postwar and depression periods. On his return from service in Panama, recognizing that the changing times required a closer cooperation between engineers and contractors than was customary before the war, he organized the Parklap Construction Corporation and Parklap Incorporated, the former to undertake heavy construction work, the latter for building construction. These companies were entities independent of the firm, and were operated under Mr. Douglas as president. They were highly successful; in the brief period of less than ten years, between 1920 and 1930, they completed more than fifty million dollars worth of construction.

The Parklap companies constructed Sherman Island Dam and Power House; Feeder Dam Power House; railway and harbor terminals at Detroit, Toronto (Ontario, Canada), Montreal (Quebec, Canada), Buffalo (N. Y.), and Albany (N. Y); wharves and bulkheads at Detroit, Buffalo, and Habana; and certain sections of the Detroit-Windsor Vehicular Tunnel. A subsidiary organization in Florida constructed the Tampa Union Terminal, the St. Petersburg News Building, the St. Petersburg Recreation Pier, and various wharves and bulkheads at St. Petersburg, Belleair, and Fort Pierce.

Mr. Douglas was a member of the Phi Delta Theta fraternity. He was also a member of the Institution of Civil Engineers of England; the Society of American Military Engineers; the Plainfield Country Club of Plainfield, N. J.; the Army and Navy Club of New York City; the Engineers' Club of New York; the Union Club of Washington, D. C.; the Army and Navy Club of Washington, D. C.; the American Society for Testing Materials; the American Railway Bridge and Building Association; and the Washington Society of Civil Engineers.

From 1919 until his death, his home was in Plainfield, where he was a member of the Grace Episcopal Church. He served on the Board of Appeals of the city Building Department and for several years was chairman of the local committee on Unemployment Relief. He died in New York City on July 2, 1941, and is buried in Hillside Cemetery, Plainfield.

He was married to Elizabeth Appleton Spalding on April 17, 1906. He is survived by his widow; four children—Walter Spalding Douglas (Jun. Am.

Soc. C. E.), Mary Virginia Crawford Douglas (Mrs. Philetus Holt Riley), Elizabeth Appleton Douglas, and Caroline Hewetson Douglas; and two grandchildren.

Mr. Douglas was elected a Member of the American Society of Civil Engineers on April 3, 1907.

ERNEST WERNER EICKELBERG, M. Am. Soc. C. E.[1]

Died May 20, 1941

Ernest Werner Eickelberg was born in Haskins, Ohio, on March 25, 1890, the son of the Rev. Hugo and Selma (Kaiser) Eickelberg.

In spite of the meager salary which the father received in the ministry, the family of five sons and five daughters was well managed and well clothed, living their lives with pride and personal happiness, thanks to the mother's diligence and versatility and the father's ingenuity, as well as to the willing sacrifices of both parents.

Ernest was the fourth child. He attended grammar schools in Buffalo, N. Y., and Baltimore, Md., finishing his last five years of public school in the latter city, where he was graduated with honors from the Baltimore Polytechnic Institute in 1910. During his high school days he worked after school and on Saturdays at a grocery and also worked in the circulation department of the *Baltimore News.* He had an inherent aptitude for mathematics. In his early youth he displayed a natural teaching ability by assisting his brothers and sisters in their school work; and later during his Polytechnic days he was frequently sought as tutor by some of his classmates. The genial disposition and patience so well remembered by all his friends of later years were notable also during these early school days.

Ernest Eickelberg entered Cornell University, at Ithaca, N. Y., in the fall of 1910, and in three years obtained the degree of Civil Engineer. His cheerful smile and willingness to do more than his part of any work attracted all who met him.

During his days at Cornell, he found time for basketball and track, which he greatly enjoyed. He usually attended church services at least once every Sunday.

While at Cornell he met O. M. Leland, M. Am. Soc. C. E. (formerly a field engineer in the U. S. Coast and Geodetic Survey and later Dean of Administration, Institute of Technology, at the University of Minnesota, in Minneapolis), and through this association he became interested in geodetic field work. In his senior year he sought connection with that service and was notified to report a few days before his own graduation exercises. His interest in this work was so intense that his roommate and close friend, Harry Barnard, was able only with great difficulty to persuade him to remain for the commencement exercises, even though his sister, Martha, who had just been married, was coming to the graduation exercises on her honeymoon.

---

[1] Memoir prepared by Paul A. Smith, M. Am. Soc. C. E.

Ernest Eickelberg joined the Coast and Geodetic Survey on June 20, 1913, and during the remainder of his life he had opportunity to demonstrate his unusual versatility in every phase of the Survey's work. Among his first assignments were wire drag surveys and launch hydrography surveys in Maine, Massachusetts, and Florida, and in Clarence Strait, Alaska. For the latter he was chief of party. During the winter of 1915–1916, he conducted second-order and third-order coastal triangulation operations in the Patapsco River region and in Baltimore, Md. In the summer of 1916 he went again to Alaska on triangulation, topography, and wire drag work. The following winter, 1916–1917, was spent in triangulation operations around San Francisco Bay, California; and in the summer of 1917 he again returned to Alaska on first-order triangulation and reconnaissance work.

In September, 1917, he was commissioned First Lieutenant in the U. S. Coast Artillery Corps, assigned to the mine planter, *Graham,* and given command in April, 1918. He was promoted to the rank of Captain in September, 1918. During this tour of duty he had charge of the laying and testing of mines and controlling cables.

On June 6, 1919, he returned to geodetic work as chief of party, and until January, 1921, was engaged in gravity observations, testing new gravity equipment, and on first-order triangulation and base measurements in California, Oregon, and Idaho. After spending a few months on office computations, he returned to field work in April, 1921, in the vicinity of Puget Sound, Washington. During the winter of 1921–1922 and the following year he accomplished the first-order triangulation connections between British Columbia, Canada, and the United States.

From March, 1922, to February, 1923, he was in charge of the computing office of the Coast and Geodetic Survey at Manila, Philippine Islands, where he superintended the adjustment of the triangulation nets of the Philippine Islands. From February, 1923, to May, 1924, he was assigned to the ship *Pathfinder* as executive officer. He took an opportunity to return to the United States by way of Europe, and his knowledge of some of the European languages, coupled with his sense of humor and genial character, made his trip around the world one that provided him with many interesting memories which he frequently related to the great enjoyment of his friends.

Returning to the United States in August, 1924, he spent the winter in charge of the District of Columbia-Virginia boundary survey. In February, 1925, he reported to the Survey Ship *Lydonia* as executive officer, where he remained on coastal surveys of the Atlantic Coast of the United States until January 18, 1926. This vessel was engaged in experimental work in radio acoustic ranging and echo sounding, and "Eick" (as he was by then universally known in the Survey) soon showed his ability in this work. He was accordingly sent to the Survey ship *Surveyor* in the fall of 1926, and later to the *Discoverer* in the Hawaiian Islands, to install echo sounding apparatus and instruct field engineers in its use. Eick was trained in this work by Dr.

Herbert Grove Dorsey, popularly known throughout the Survey as "Doc." As a mark of distinction for his outstanding ability, Eick was promptly dubbed "Doc" also by his colleagues in the Survey, a title which stuck with him for many years.

In January, 1928, he returned to the *Lydonia* and worked on Atlantic coastal surveys until June, 1929. During this assignment he was married to Mary Louise Stover in Wilmington, N. C., on April 10, 1928. He assumed command of the Survey ship *Explorer* in June, 1929, operating on topographic, hydrographic, and geodetic surveys in Southeastern Alaska.

Eick returned from this assignment in August, 1931, to the position of assistant chief, Division of Terrestrial Magnetism and Seismology of the Survey in Washington, D. C. Here he was active in the development of new methods and procedures, as a valued assistant to Capt. N. H. Heck, M. Am. Soc. C. E.

In August, 1938, he returned to the Pacific Coast in command of the Survey ship *Guide,* and conducted difficult and important surveys in the Bering Sea in the vicinity of Unimak Pass, Alaska. During this assignment he was stricken in the summer of 1940 with the first indication of the disease that eventually caused his death. He was confined to the hospital in Dutch Harbor, Aleutian Islands, Alaska, for several months following a serious operation; upon apparent recovery he returned to Oakland, Calif., and subsequently to Washington, D. C., where he had received orders to become assistant chief of the Division of Coastal Surveys. The last months of his life were spent at the Marine Hospital in Baltimore. Here his genial smile never failed to greet his many friends from Baltimore and Washington, D. C., who visited him, in spite of the pain he endured without complaint until his death.

Eick was slight and wiry in build, but his character raised him above many of his colleagues in those modest personal qualities that make for outstanding leadership. On mountain trails, surf landings on dangerous coasts, and in any of the hardships frequently encountered in the field work in which he spent almost twenty years of his life, he always led the way with more than his share of the undesirable chores and burdens.

He was always a willing participant in any of the playful badinage commonly indulged in by members of survey parties in remote places. On one occasion he cheerfully permitted himself to be hauled by a line through glacier streams by several of his fellow engineers when they discovered that he was too light to ford the numerous swift and icy streams flowing into the sea from the Fairweather Range south of Lituya Bay, Alaska, and along which coast his party was running a control survey.

During his service with the Survey, he rose to the rank of Lieutenant-Commander, and at the time of his death was one of the most popular senior officers in the service. He was active in sports, especially golf and bowling, and usually held office as secretary or treasurer of the sports association in spite of his heavy administrative duties.

Commander Eickelberg always became an active participant in the life of the community where he resided with his family. He was especially well known in Arlington, Va., where he lived during his last duty in Washington, D. C., and where funeral services were held in St. Mary's Episcopal Church. Burial was in Arlington National Cemetery with military honors. He is survived by his wife; a daughter, Jean Stover; a son, Ernest Werner; and all of his brothers and sisters, who are Hugh, Erwin H., Arthur P., Dr. Walter A., Helen I., Martha (Mrs. E. O. Youngen), Selma (Mrs. William C. Miles), Clara (Mrs. Charles E. Lyon), and Edna R. (Mrs. H. Middleton Heer).

He was a member of Dawson Lodge No. 16, F. and A. M., in Washington, D. C., the Philosophical Society of Washington, Society of American Military Engineers, Washington Academy of Sciences, American Geophysical Union, American Society of Photogrammetry, Society for Research on Meteorites, Sojourners, and Heroes of '76.

The signature "E. W. Eickelberg" is probably found on as wide a variety of survey observations and records as that of any engineer in the service. His resourcefulness in devising improvements to surveying apparatus and instruments was notable. Some of these improvements are described in various technical reports and papers under his name in the archives and publications of the Coast and Geodetic Survey. His meticulous concern for thoroughness, accuracy, and a job well done was outstanding in the organization whose work he enjoyed so well, and from whose personnel he won the highest tribute a man may have—the confidence of his superiors, the esteem of his associates, and the respect and loyalty of his subordinates.

Commander Eickelberg was elected an Associate Member of the American Society of Civil Engineers on April 25, 1921, and a Member on October 14, 1935.

NATHAN RANDALL ELLIS, M. Am. Soc. C. E.[1]

DIED FEBRUARY 28, 1941

Nathan Randall Ellis was born in San Francisco, Calif., on January 5, 1876, the son of Nathan Rodney Ellis and Katherine (Quigley) Ellis. He attended the historic Lincoln Grammar School and Boy's High School in San Francisco, developing a remarkable aptitude for mathematics. Unable to continue his educational course through college, he remained a diligent and conscientious student throughout his life.

Upon graduation from high school in 1894, he immediately found employment in the construction of a water power plant on Mokelumne River. The first successful utilization of water power for the generation of electricity for commercial use in California had been effected only two years previously, and in 1894 there were four additional plants under construction in the state, and a large number in various stages of study and projection. This Blue Lakes plant on the Mokelumne River, when completed in 1897, was the fourth California installation of this kind to be placed in operation, and the first to supply service from transmission lines operated at the then unprecedented potential of 17,000 volts. These pioneer installations were of primary importance in demonstrating the extent and complexity of the physical, technical, economic, industrial, and financial problems confronting the development of California's vast water resources.

---

[1] Memoir prepared by Paul Leo Beck, M. Am. Soc. C. E., and James Tillman Ryan, Assoc. M. Am. Soc. C. E.

To the young high school graduate, these problems presented both a challenge and an opportunity. He responded to this by entering upon a course of self-directed study in engineering with characteristic energy and thoroughness, using all the available textbooks and current literature, but, to a more important degree, the personal instruction and example of engineers to whom he reported in the practical work of design and supervision on the job.

The Blue Lakes Water Company realized, even before the completion of its first plant, that the power service it proposed to supply required far more capacity than it could develop at that site or could finance from its available resources. It was, therefore, reorganized as The Standard Electric Company of California, which was incorporated on November 27, 1897. With Mr. Ellis employed in successive positions of increased responsibility, the company began the studies that resulted in the construction of the Electra plant, at a point 4 miles upstream from the Blue Lakes plant, and an extensive system of canals and reservoirs to supply water for its operation. Actual construction was begun in July, 1900, with Mr. Ellis assigned to the supervision of all work except the power-house equipment and penstocks. Thus, he was already well advanced in his chosen field at the age of twenty four.

His work from 1894 to 1900 was, therefore, both an apprenticeship and the equivalent of a college course in engineering, his diploma for the latter being his appointment as superintendent. In this capacity he designed and constructed two diversion dams in the main channel of Mokelumne River, five storage and two forebay reservoirs, and a canal 22 miles long with a flow capacity of 125 cu ft per sec. He also superintended the reconstruction and enlargement of a parallel canal 21 miles long with a flow capacity of 75 cu ft per sec. This work was completed and the plant placed in operation on May 6, 1902.

The excellence of its design and construction is attested by the fact that all of it has been in continuous operation since, except the diversion and intake structures, which were by-passed by the Tiger Creek power plant, completed in 1931. Probably one of the most significant things that Mr. Ellis ever did was to turn over to the Pacific Gas and Electric Company a complete report of construction methods and progress and an analysis of the cost of this project.

In the latter part of 1904 he was appointed manager of the Humboldt Construction Company, the work involving electric railway construction and the installation of a steam power plant for the local railway system in Eureka, Calif. In the early part of 1906 he became chief engineer and assistant general manager of the Shattuck-Edinger Construction Company, which was engaged in the construction of the Northern Electric Railway, the Western

Pacific Railroad between Oroville and Sacramento, Calif., and the Southern Pacific Railroad from Santa Cruz to Vicente, Calif.

During 1907 he was employed as the engineer for the contractor on the construction of the Market Street sewer system in San Francisco. This was a cost-plus contract and, as the total cost greatly exceeded the preliminary estimates, the contractor was charged with gross waste and inefficiency, culminating in an investigation by the Grand Jury. After a thorough investigation, the Grand Jury not only cleared the contractor but in addition commended Mr. Ellis for the efficient conduct of the work. This commendation was due in part to the fact that he maintained and was able to present a complete record of construction methods and costs.

In 1908 Mr. Ellis was appointed engineer in charge of construction for the Crocker Estate Company in San Francisco on the subdivision of the Crocker Estate. This is now largely that part of Daly City, Calif., which lies east of Mission Road.

In the latter part of 1908 he became manager of the Desmond Construction Company in Los Angeles, Calif. In this capacity he supervised the construction of the Inter-California Railway in Mexico and the Arizona-Colorado Railroad in Arizona, and a reconstruction of the Gila Valley, Globe and Northern Railroad in Arizona. In addition to this railroad work, Mr. Ellis directed the Desmond Company's subsistence and commissary contracts on the Los Angeles Aqueduct, operating some fifty camps and dining rooms. On the cessation of work on the aqueduct in 1910, he became office engineer for the Los Angeles Highway Commission, which was engaged in the construction of highways costing some three and a half million dollars. In 1911 he became a partner in the contract for the construction of the Interurban Electric Railways from Van Nuys to Canoga Park in the vicinity of Los Angeles.

His first contact with valuation work was made in November, 1911, as an assistant engineer for the J. G. White Company of San Francisco on an appraisal of the properties of the Spring Valley Water Company. In July, 1912, he was appointed consulting engineer for the Finance Committee of the Board of Supervisors of the City and County of San Francisco to study the functions of the various departments of the Board of Public Works. In the street repair department he made exhaustive studies of paving methods and costs, resulting in the reorganization of that department. He also made similar studies of the operations of the sewer department, the street cleaning department, and the department of buildings.

On the completion of this work in August, 1913, Mr. Ellis was appointed valuation engineer for the city attorney's office of San Francisco. From 1913 to 1932 he supervised the following valuations: Spring Valley Water Company, appraised twice; the gas and electric properties of the Pacific Gas and Electric Company in San Francisco; all of the properties of the Pacific Gas and Electric Company's gas and electric system in California, as well as all of the properties of the Great Western Power Company, later merged with the Pacific Gas and Electric Company; and properties of the Pacific Telephone and Telegraph Company in San Francisco and the East Bay Cities in

1913 and 1914 and again in 1927. He was also in charge of the preparation of evidence presented by the city attorney in all utility rate cases before the Federal Court and the Railroad Commission of the State of California.

Mr. Ellis' activities were not confined to the rate work and valuation work of the city attorney. He was frequently called in as a special advising engineer to the Board of Supervisors on the operation of the city's municipally owned utilities, programs of construction on the Hetch Hetchy Project, and in proceedings looking to the acquisition of the water and electric properties in San Francisco. From 1913 until 1932, he was at various periods employed as consulting engineer on valuation and rate matters by the cities of San Jose, Marysville, and Fresno (all in California), and by the Sierra Railway Company of California and the McCloud River Railroad Company in proceedings before the Interstate Commerce Commission.

With the ratification of a new charter by the electorate of the City of San Francisco in 1932, Mr. Ellis' title was changed to chief valuation and rate engineer. From 1932 until his death, he continued to supervise the preparation of all data presented by the city attorney before the Railroad Commission of the State of California in cases involving gas, electric, and telephone rates and street railway fares. He also advised and reviewed the reports of the Public Utilities Commission of the City and County of San Francisco on the cost of acquiring the electric properties of the Pacific Gas and Electric Company, and the financial results to be expected under municipal operation. The last important report prepared by Mr. Ellis was on the financial results to be derived from the leasing of the electric distribution properties of the Pacific Gas and Electric Company in San Francisco.

Randall Ellis faced the problems and issues of life with resolute courage and discharged his duties with conscientious integrity. To him there was but one standard of right, but one measure of excellence, and to these he exacted even more rigid conformity from himself than he expected from others. With these principles and with a positive and aggressive mentality, a man whose pathway constantly led through fields of controversy must needs beget opposition. He was a participant in a number of the most important and bitterly contested rate and condemnation cases in American court history, in which he was on successive occasions in opposition to many of our most famous technical experts and subjected to cross-examination by some of the most adroit practitioners of the American Bar. The significant result of all of these cases was the very great extent to which the final decision in each conformed to Mr. Ellis' analysis and conclusions.

In a condemnation case involving the most valuable property ever subject to such proceedings in America, he arranged for a series of conferences with engineers representing the various interests involved. These resulted in the presentation of an appraisal that was accepted by all and adopted by the Commission which decided it. In numerous proceedings involving the rates of utilities, with hundreds of millions of invested capital and hundreds of thousands of customers, it was not infrequent that he was able to bring all parties concerned into agreement as to the pertinent facts, leaving only questions of policy for argument and decision.

These controversies usually extended into months and several of them into years of intensive study and patient analysis. The ultimate agreement was reached only after Mr. Ellis had established the soundness of his own logic, and had virtually shamed prejudice from its bias, entrenched interest from its selfishness, and political objective from its subterfuges.

The esteem in which Mr. Ellis was held was probably best expressed by Resolution No. 1658 (Series 1939) of the Board of Supervisors of the City and County of San Francisco, as follows:

> "WHEREAS, Almighty God has summoned to eternal rest, N. Randall Ellis, utility rate expert for the City and County of San Francisco; and
>
> "WHEREAS, Mr. Ellis, for twenty-five years an employee of the City and County, participated in all important rate litigations involving San Francisco, and immediately prior to his death was engaged in a study of electric power distribution facilities of the Pacific Gas and Electric Company, in connection with the proposed City lease thereof; and
>
> "WHEREAS, the affability of Mr. Ellis was, to his many friends and colleagues, of equal distinction with his worth as a man of erudition, expert in his chosen field, and his passing will be a distinct loss to San Francisco and his death deeply mourned by his many friends in private and public life;
>
> "Now, therefore, be it resolved, that this Board notes with keenest regret the passing of N. Randall Ellis, and when it adjourns this day it does so out of profound respect to his memory; and the Clerk is hereby directed to forward to his bereaved widow and family a copy of this Resolution as an expression of the Board's heartfelt sympathy and condolence."

Mr. Ellis was married to Clara Cook at Mokelumne Hill, Calaveras County, Calif., on December 31, 1901. They became the parents of three daughters, Eleanor (Mrs. Donald Mazer), Edith, and Katherine Elizabeth (Mrs. Donald Fleming), who, with Mrs. Ellis, survive him.

He was a Registered Professional Civil Engineer of the State of California, and a member of the American Water Works Association and Commonwealth Club of San Francisco.

Mr. Ellis was elected a Member of the American Society of Civil Engineers on June 23, 1916.

JULIAN CLARENCE FEILD, M. Am. Soc. C. E.[1]

DIED DECEMBER 22, 1940

Julian Clarence Feild was born in Denison, Tex., on September 9, 1881, the son of Julian Clarence and Susan Elizabeth (McClain) Feild. His father was a physician in the rapidly opening Southwest and a leader of community activities, having chosen to make Denison his home shortly after the townsite was established in 1872 by the builders of the Missouri, Kansas and Texas Railway. His mother was of a pioneer family that went to Texas many years previously and had settled at Whitesboro. His boyhood was spent in the frontier town, where he attended the public schools and Harshaw's Literary Academy.

---

[1] Memoir prepared by A. M. Brenneke, Assoc. M. Am. Soc. C. E.

His higher education began with one year at the University of Texas, in Austin, after which he transferred to Cumberland University at Lebanon, Tenn., where he was graduated in June, 1902, with the degree of Bachelor of Science. During vacations he gained valuable experience in survey parties with various railroads expanding throughout Texas and Oklahoma.

After graduation it was natural for him to continue in railroad location and construction, which he did until May, 1907, first as assistant engineer for the Shreveport and Red River Valley Railroad Company; then as draftsman and instrumentman with the St. Louis-San Francisco Railway and the Missouri Pacific Railroad companies; and finally as division engineer of construction on the Springfield Division and as division engineer on the Colorado Division of the Missouri Pacific Railroad Company.

In May, 1907, he decided to open his own office in Denison for general engineering practice. During the next ten years he served four years as construction engineer and one year as city engineer for Denison; two years as county engineer, Grayson County; as consulting engineer for Grayson, Hunt, Robertson, and Milam counties on $2,000,000 worth of road construction; and as consulting engineer for the Southern Surety Co., Lion Bonding and Surety Company, and Fidelity and Bonding Company, advising on contract bonds and adjusting losses. As consulting engineer for the Red River Bridge Company, he designed and built a highway and interurban bridge over the Red River, near Denison, in 1914. It was during this period that rapid strides were being made in road construction, in which move Julian Feild was an active leader both as an organizer of the Texas Good Roads Association and as consultant for the Oklahoma, Texas and Gulf Highway Association and the Jefferson Highway Association.

In 1916, he became associated with the Healy Construction Company in the construction of streets and roads. While connected with this company he built many miles of improved roads around Pine Bluff, Grady, Hope, and Prescott, Ark. His ability as an organizer and his keen foresight led him to continue road contracting work, from 1920 until about 1931 under the firm name of Julian C. Feild and Company, and his was a pioneer firm in concrete road construction in the Southwest. Julian C. Feild and Company built concrete roads during the decade following the first World War in many counties in Texas, doing a volume of business often in excess of $1,000,000 annually. In the early 30's contracting became less interesting to him, and he fulfilled an earlier desire to enter the construction material business by building a sand and gravel plant just north of Denison, which plant he operated until his death.

Julian C. Feild had a keen interest in, and sense of individual responsibility toward, all civic activities and took an active part in community development. He was President of the Denison Chamber of Commerce for two years, 1927 and 1928, a director of the State National Bank, President of the Denison Hotel Company, and a director of the Denison Building and Loan Association. He was a lifelong member of St. Luke's Episcopal Church, in Denison, and served as Senior Warden and as a Vestryman for many years. He was a Thirty-Second Degree Mason, a member of the Denison Rod and Gun Club, Denison Rotary Club, and Beta Theta Pi fraternity.

He was married on June 10, 1903, at Lebanon, to Mary Lea Sanders, whom he met and won while a student at Cumberland University. One daughter, Kathryn Elizabeth Feild, was born of this union. He is survived by his widow and his daughter.

Mr. Feild was elected an Associate Member of the American Society of Civil Engineers on January 17, 1916, and a Member on November 27, 1917. He was active in the organization of the Texas Section of the Society in 1913, being one of those present when such an organization was proposed, and he assisted in the organization activities.

JAMES EASTON FERGUSON, M. Am. Soc. C. E.[1]

Died March 3, 1941

James Easton Ferguson, who died on March 3, 1941, at his residence in Cleveland, Ohio, at the age of sixty five, had been manager of the Fabricating Division of The Austin Company, Engineers and Builders, for a period of twenty-one years, during which he played an important rôle in the development of efficient methods for shop welding of structural steel.

A native of Marshall, Mich., where he was born on April 21, 1875, the son of Thomas E. and Margaret (Porter) Ferguson, Mr. Ferguson attended public school and high school at Toledo, Ohio, and in 1894 entered Cornell University, at Ithaca, N. Y. Prior to entering college he had spent one year as assistant to the manager of the Cincinnati, Hamilton and Dayton Railway Elevator Company at Toledo, handling general work and assisting in the supervision of construction of a grain elevator. He continued this work during the succeeding summers. Upon completion of his studies in civil engineering at Cornell in January, 1898, Mr. Ferguson obtained his first regular employment with the Toledo Bridge Company (later a part of the American Bridge Company). As draftsman and estimator he was engaged in the detailing and checking of shop drawings from January, 1898, until October, 1900. He spent the following six months there designing and estimating highway bridges and mill buildings. From March, 1901, to March, 1902, he was chief draftsman of the Macdonald Engineering Company in Chicago, Ill., in charge of structural design and drawing room, on work which included design and detailing steel for several fireproof, steel, grain elevators representing an aggregate investment of about

---

[1] Memoir prepared by W. G. Paton, M. Am. Soc. C. E., and Louis H. Burr, Mgr., Fabricating Div., The Austin Co., Cleveland, Ohio.

$1,500,000. During this period he also supervised shop and field work on these projects.

In March, 1902, he went to Detroit, Mich., as assistant engineer for the American Bridge Company in that area, and was in charge of the drawing-room squad, with direction over the detailing for various classes of bridges and buildings. Mr. Ferguson continued in this capacity until June, 1906, when he joined the Toledo-Massillon Bridge Company at Toledo, serving as chief draftsman and assistant plant engineer until May, 1908. He was in complete charge of detail design and drawing-room work for railroad and highway bridges and buildings for fabrication at the Toledo and Massillon plants. From May, 1908, to January, 1909, as contracting engineer, he made designs and estimates for all classes of bridge and building work and handled some contracting. Following some erection work during this period, he had charge of the construction of a $200,000 highway and street railway bridge over the Monongahela River between Webster and Donora, Pa., where the channel span was 515 ft long. In this connection, he designed the falsework, travelers, and erection schemes. From 1909 until 1917, when he left the company, Mr. Ferguson functioned first as plant and construction engineer in full charge of shop operation, construction work, drafting department, and steel purchases, and later as operating manager. In the latter capacity he was directly responsible for the fabrication and erection of the Cherry Street Bridge[2] at Toledo and several large bridge projects in the Chicago area, all of which were bascule span bridges.

Leaving the Toledo organization in 1917, Mr. Ferguson assumed the responsibilities of general management at the American Steel Company of Cuba at Habana, which at the time operated a structural steel plant, railroad car plant, and a bolt and rivet works. In this capacity he was closely connected with the expansion of Cuba's industrial plant facilities, particularly for the sugar industry, for which the American Steel Company produced a large number of new freight cars. He left Cuba at the end of 1918, returning to Toledo, where he established his own consulting engineering service and collaborated in the design of additional bridges and industrial structures in the Middle West.

He joined The Austin Company, Engineers and Builders, as manager of its Manufacturing Division in Cleveland on April 1, 1920, and in that capacity, for the succeeding twenty-one years, was largely responsible for the development of the efficient shop practices that have distinguished this plant. Under his management, the plant was expanded repeatedly and grew from a capacity of between 300 and 400 tons per month in 1920 to a capacity of approximately 1,800 tons per month in 1941.

The standard cross sections developed by Austin engineers during the previous decade, and which figured so largely in construction of defense plants for the first World War, were produced in large quantities and at record speeds during the factory building boom of the middle 1920's. It was largely as a result of Mr. Ferguson's organizing ability and his understanding of production problems that his plant, one of the smallest in Ohio, was able to produce more tonnage than other shops twice its size. During one month in 1925, for instance, the plant fabricated 1,031 tons of structural steel in a shop area of less than 7,500 sq ft.

---

[2] "The Cherry Street Bridge, Toledo, Ohio," by Clement E. Chase, *Transactions*, Am. Soc. C. E., Vol. LXXX, December, 1916, p. 744.

With the introduction of electric welding, the Austin shop became a center of research and experimental work in this field. It was under Mr. Ferguson's direction that the shop developed test procedures and set up equipment for the efficient fabrication of structural elements by welding. Structural members for a 50-ton crane runway at the Pittsburgh Transformer Company, later a part of the Allis-Chalmers Company, constituted the first commercial tonnage handled at this shop. In 1929 the shop furnished steel for a four-story and basement store and office building, which The Austin Company built as an investment and to gain practical welding experience before it undertook the design and construction of welded plants on a commercial basis. This building was erected entirely without the aid of rivets and temporary bolts. After the difficulties encountered in erecting the 117 tons of steel for this structure, Austin engineers recognized the importance of adequate temporary field connections and Mr. Ferguson played a major part in working out these problems.

With one corner equipped with special grids which expedited fabrication, the shop in 1930 promptly turned to jig welding of trusses for a long series of industrial plants. Although many of these conform to standard Austin cross sections, a variety of special designs demonstrated the widespread adaptability of welding.

Most significant of all the jobs undertaken at the Austin shop, under Mr. Ferguson's direction, was the fabrication of 2,600 tons of structural steel for the Electro-Motive Corporation's Diesel Locomotive Works at La Grange, Ill., in 1935. Designed for production of Diesel locomotives weighing up to 200 tons, this plant called for roof trusses of 104-ft span and built-up columns 65 ft high, weighing 6 and 7 tons, respectively, in its main erection aisle, where one 200-ton electric traveling crane and two cranes of 30-ton and 40-ton capacity were to operate. The extent of shop welding on this project is indicated by the fact that only 17% of the welding electrodes (totaling 7½ tons) were used in the field.[3]

When the Austin research organization during the early depression years initiated studies into ways and means of providing more clean-cut, sturdy factory cross sections, experiments were executed under Mr. Ferguson's supervision at the fabricating shop. Late in 1936 the shop turned out columns and roof bents for one bay of an all-welded, rigid-frame, saw-tooth structure in which "tree-form" curves supplanted the angles normally encountered at roof and column connections. Several months later the shop produced its first commercial tonnage, applying this cross section for the International Silver Company. This was followed in July, 1937, by the fabrication of 1,327 tons for the Lincoln Electric Company's addition, where four 40-ft aisles, ranging from 240 to 442 ft in length, involved the use of this cross section, and where a lofty, all-welded, 80-ft "cathedral" aisle, 39 ft to the peak, was also provided.

Steel for a series of other welded, rigid-frame, saw-tooth plants was fabricated under Mr. Ferguson's direction. These were followed by fabrication of welded rigid-frame portal trusses, which Austin utilized to accommodate conveyers in otherwise useless sub-ceiling areas immediately under factory roofs. This was accomplished by eliminating diagonal truss members and was tested at the fabricating shop, where the cross section was applied experimentally in a building addition. This application of the portal truss principle was used in a fertilizer plant built for the International Agricultural Corporation at Chicago Heights, Ill., in 1938.

---

[3] "Welding in the Design and Construction of Industrial Plants," by Albert S. Low, *The Welding Journal*, Am. Welding Soc., May, 1940, p. 329.

A total of more than 60,000 tons of steel was welded at the Cleveland shops under Mr. Ferguson's management and included the framework for several hundred buildings, among which are the American Rolling Mill Company's research laboratory at Middletown, Ohio; a bicarbonate of soda plant at Syracuse, N. Y.; the controlled-conditions factories of Simonds Saw and Steel Company, at Fitchburg, Mass.; and the Allison Division of General Motors in Indianapolis, Ind.

Essentially a "family man," Mr. Ferguson's chief interest was always in his wife, the former Bessie Norris of Toledo, to whom he was married in 1900, and his four children, Edmund Easton, Thomas Warner, Norris Porter, and Elizabeth (Mrs. R. E. Daus). An occasional golfer in earlier years, his primary source of active recreation was motoring, and he was known to have driven as many as 725 miles, just for the love of it, on a Sunday.

He was an occasional contributor to technical publications, and served on arbitration boards and as an expert witness in court cases involving structural practices. He was a member of the American Welding Society and was a registered professional engineer for civil and structural work in the State of Ohio.

Mr. Ferguson was elected an Associate Member of the American Society of Civil Engineers on June 1, 1904, and a Member on January 3, 1911. He became a Life Member on January 1, 1939.

FRED EUGENE FOSS, M. Am. Soc. C. E.[1]

DIED JANUARY 18, 1942

The friends and associates of Prof. Fred Eugene Foss were deeply grieved at his passing on January 18, 1942, at Bethesda, Md.

He was born at Wales, Me., on June 11, 1862, the son of Uriah and Abby (Furlong) Foss. A practical viewpoint inherited from his New England parentage was evidenced in his splendid sense of proportion and his well-balanced judgment throughout his active professional life.

He was graduated from Bates College at Lewiston, Me., in 1883 with the degree of Bachelor of Arts, and in 1886 he received the degree of Master of Arts from the same institution. Following his graduation from Bates, he enrolled in the course in civil engineering at the Massachusetts Institute of

---

[1] Memoir prepared by R. C. Brumfield and Elton D. Walker, Members, Am. Soc. C. E.

Technology in Boston, Mass., from which he was graduated in 1886 with the degree of Bachelor of Science. Later, Bates College conferred upon him the honorary degree of Doctor of Science.

From 1886 to 1889 he was employed by the Minnesota and North Western Railroad Company (later the Chicago, St. Paul and Kansas City Railway Company, and, still later, the Chicago, Great Western Railroad Company) in the various grades of transitman, resident engineer, and assistant engineer of maintenance of way. From 1889 to 1891 he was employed as resident engineer by the Chicago Union Transfer Railway Company.

In 1891 Mr. Foss returned to the Massachusetts Institute of Technology as instructor in civil engineering to arrange the material for, and to teach, a new course in railway and highway engineering. In 1893, after two years at the Institute, he went to The Pennsylvania State College at State College, Pa., as head of the Department of Civil Engineering. Here he installed the first hydraulics laboratory at the college, and had an important part in the development of the testing materials laboratory. In addition to his teaching work he was engaged in engineering practice that included work as borough engineer for State College from December, 1900, to June, 1906.

In 1907 Professor Foss resigned his position at The Pennsylvania State College to accept an appointment as head of the Department of Civil Engineering at Carnegie Institute of Technology in Pittsburgh, Pa. He remained at Carnegie Institute until 1909, when he went to New York, N. Y., as head of the Department of Civil Engineering at The Cooper Union. He held this position until his retirement as Professor Emeritus in 1938.

During his period of service as head of the Department of Civil Engineering at The Cooper Union, the Department expanded several fold in both personnel and in its services to the students of the institution. Particularly notable among the accomplishments of Professor Foss during this period was his work in planning and installing the Materials Testing and Hydraulics Laboratories. These laboratories are unique in the completeness and compactness of their equipment, and in the opportunities for experimental work which they offer to the student body. Professor Foss served as Secretary to the Faculty from 1914 to 1938, and exerted a great influence on that body through his gentlemanly qualities and sound judgment.

While he was at The Cooper Union, he also served for eighteen years as engineering examiner for the Municipal Civil Service Commission of New York City.

Professor Foss's long teaching service was interrupted by two leaves of absence, each for one year. During his first leave he took the position of principal assistant superintendent of construction for the J. G. White Engineering Corporation on the construction of the Raleigh and Pamlico Sound Railway from 1906 to 1907. During his other leave he was director of the Physical Testing Laboratories, Ordnance Department, United States Army, in the first World War.

Undoubtedly, one of the greatest of Professor Foss's many quiet achievements during his long engineering career was his spiritual influence on the many students with whom he came in contact. No class left him without the impress of his fine engineering knowledge and the splendid example of gentlemanly qualities which he embodied. Such achievements are difficult to measure, but they are very important.

Professor Foss did committee work for the National Research Council during the first World War. He was a Director of the Railroad Cooperative Building and Loan Association. He was a charter member of the Society for the Promotion of Engineering Education and a life member of the American Railway Engineering Association. He held membership in the American Society for Testing Materials, American Road Builders' Association, Sons of the American Revolution, Phi Beta Kappa fraternity, Phi Kappa Phi fraternity, The Seigniory Club of Quebec, and Lucerne-in-Maine Country Club. He was a member of the Board of Governors of the latter club.

He was married three times: In 1889 to Mittie Hanscom at Oak Park, Ill.; in 1908 to Louise Rust at Cleveland, Ohio; and in 1939, in New York City, to Jane Emerson Chadbourn, who survives him.

Professor Foss was elected a Member of the American Society of Civil Engineers on April 1, 1903, and became a Life Member in January, 1933.

HENRY NEWTON FRANCIS, M. Am. Soc. C. E.[1]

Died February 28, 1942

Henry Newton Francis, the eldest son of Blinn and Lucy (Hart) Francis was born in West Hartford, Conn., on November 6, 1853. He was the second eldest of a family of nine children. His father was a building mover. Both parents were Connecticut Yankees.

Mr. Francis was educated in the elementary schools of West Hartford and spent part of two years in the Hartford, Conn., High School. In the spring of 1871 he went to Cranston, R. I., where he was employed by the City of Providence, R. I., as a junior engineer under the late Samuel M. Gray,[2] M. Am. Soc. C. E., on the new water supply then being built. He continued on this work until its completion, about 1877, when he became connected with the city engineer's office in Providence as an assistant engineer in charge of various street, sewer, bridge, and harbor improvement projects, as well as further extensions of the water supply system.

In 1893 Mr. Francis became superintendent of the Narragansett Improvement Company of Providence, which was engaged in laying asphalt paving in Providence, Newport, R. I., Woonsocket, R. I., New Bedford, Mass., Taunton, Mass., and other near-by localities. In 1901 Mr. Francis was for a short time a contractor on his own account, and then became employed as engineer for the late Frederick E. Shaw, a prominent New England contractor. In

---

[1] Memoir prepared by Paul H. Francis, Washington, D. C., and Carl Francis, Audubon, N. J.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. LXXXV (1922), p. 1679.

1913 Mr. Francis was again employed under Mr. Gray and was engaged in preliminary property surveys for acquisition of property necessary for the new Scituate Reservoir, which was a major extension of the Providence water supply system. He was one of the two engineers who were connected with the first water supply system for the City of Providence which was planned to be supplemented later by a second system. He was the only one to live to see the second system completed. He resigned and retired in 1923. His last work was the construction of the small Horseshoe Dam at North Scituate, R. I., a part of the Scituate Reservoir project.

Mr. Francis was active in politics and was a member of the School Committee, and a member and president of the City Council of Cranston for two terms. He was also a Representative for two terms from the third ward of the City of Cranston in the General Assembly of the State of Rhode Island.

He was active in fraternal organizations and was an Odd Fellow, a Red Man, a Past Sachem of Wamsutta tribe, a Past Great Sachem of the District of Rhode Island, a Thirty-Second Degree Mason, a Past Master of Nestell Lodge, a Past High Priest of Providence Royal Arch Chapter, and a member of numerous other Masonic organizations.

Mr. Francis was one of the earliest advocates of the "good roads" movement and was instrumental in starting and building many miles of water-bound macadam in his own town of Cranston about 1890. It is also interesting to note that Mr. Francis saw the economic advantages of good roads to transportation as well as to real-estate values. Probably he was one of the first engineers to sense the fact that hard-surfaced roads need a solid concrete foundation, and he put this idea into practice in the actual construction of a number of miles of streets in Providence, which stood up well under heavy travel. Easy grades, long-radius curves, and good drainage of new roads were advocated and put into use by Mr. Francis many years before it was generally realized how important they were to become in modern road construction.

He was one of the first bicycle enthusiasts, and a charter member of the League of American Wheelmen. He was also a member of the Touring Club de France and of the Cyclists Touring Club of England. He made two bicycle trips to Europe accompanied by his eldest son, Carl, and toured England, France, Italy, and Switzerland. He was also one of the early automobile owners in Rhode Island, starting in 1903 with the well-known "one-lung" Cadillac. He drove his car to Florida for the winter and returned north in the spring each year until well past eighty.

He was married to Emily Jane Pettis of Putnam, Conn., in 1878. There were three children by this marriage, two of whom, Carl and Paul Hart, survive him. Two sisters also survive him. His first wife died in 1914 and in 1917 he was married to Louise Lissette Hilkeny who died in 1939.

Mr. Francis was elected a Junior of the American Society of Civil Engineers on March 1, 1876, and a Member on November 7, 1888. At the time of his death he was the oldest member, in years of membership, of the Society.

MANFORD W. FURR, M. Am. Soc. C. E.[1]

DIED NOVEMBER 16, 1941

Manford W. Furr was born on a farm near Veedersburg, Ind., on August 24, 1888, the son of Sylvan and Eva (Wilson) Furr. After completing the high school course at Veedersburg, he entered Purdue University at Lafayette, Ind., from which he was graduated with the degree of Bachelor of Science in Civil Engineering in 1913. He was awarded the degree of Civil Engineer by Purdue in 1925 and the degree of Master of Science by Kansas State College, at Manhattan, in 1926.

After subordinate positions of a few months each with the American Tie and Creosote Company and the Lafayette and North-Western Traction Company, he became an instructor in civil engineering at the State University of Iowa, at Iowa City, in September, 1915. In September, 1917, Mr. Furr went to Manhattan as an instructor in civil engineering at the Kansas State College. He was advanced rapidly and attained a full professorship, in charge of instruction in highway engineering, in 1927.

Manhattan was his residence during the remainder of his life, and Mr. Furr's fine character and technical ability were soon recognized in the community. He accepted many assignments to service in its civil and social activities, and was an active member of the Christian Church, serving, more than once, on building committees and for several years as treasurer and deacon. He was a member of the Manhattan Country Club and of the Chamber of Commerce, in both of which organizations he filled frequent committee appointments. For several years he was a member of the Manhattan Planning Commission.

Mr. Furr was an enthusiastic member of the Society, and of its Kansas Section. He was for several years the faculty sponsor of the Kansas State Student Chapter, and on numerous occasions took student representatives to the regional meetings. Nearly every summer, when not prevented by other work, he attended the Annual Convention of the Society and the annual meeting of the Society for the Promotion of Engineering Education (S. P. E. E.), of which society he was also a member. At different periods he was chosen as chairman of the Kansas Section of the Society, and of the Kansas-Nebraska Section and the Civil Engineering Section of the S. P. E. E. He was a member of the American Road Builders Association, the Kansas Engineering Society, and the honorary fraternities of Phi Kappa Phi and Sigma Tau.

Although primarily a teacher, Mr. Furr never missed a chance to improve his contact with outside affairs through summer work with railroads, consulting firms, or state departments. His first interest was in highway engineering. He was closely associated with the entire development of the Federal Aid System in Kansas, and he assisted with the preparation of plans for a number of the earlier projects.

---

[1] Memoir prepared by L. E. Conrad, F. F. Frazier, and C. H. Scholer, Members, Am. Soc. C. E.

On September 12, 1915, he was married to Lela Osborn in Lafayette. He is survived by his widow; his mother; a sister, Mary E. Furr; and a brother, Omer Furr.

Mr. Furr was elected an Associate Member of the American Society of Civil Engineers on January 15, 1923, and a Member on August 17, 1936.

JOSEPH GOODMAN, M. Am. Soc. C. E.[1]

Died May 9, 1941

Born in Sáros-Pâtak, Hungary, on January 14, 1876, Joseph Goodman, at the age of ten, was brought to the United States by his parents, Leopold and Amelia (Feldmesser) Goodman. At that time he became a resident of New York, N. Y., and remained so until his death.

He attended New York City public schools and later the College of the City of New York, from which he was graduated with the degree of Bachelor of Arts in 1894. He then entered the School of Mines of Columbia University, in New York City, from which he was graduated with the degree of Civil Engineer in June, 1898. His work in college was outstanding and, after graduation, he served for several months as assistant instructor in surveying at Columbia University's Summer School, near Litchfield, Conn.

In October, 1898, he entered the employ of the City of New York as a topographical draftsman and computer in the Department of Public Improvements. He served in this position until July, 1900. After a short period of private employment as structural draftsman and detailer, he re-entered the employ of the city in January, 1901, as transitman in the Bureau of Water Supply of the Borough of Brooklyn, being promoted to assistant engineer in March, 1904.

At that time, the maintenance, operation, and extension of the water supply system in the Borough of Brooklyn were under a separate chief engineer, there being a chief engineer with headquarters in Manhattan who functioned in the other four boroughs of the city. The water system of the Borough of Brooklyn was unique, in that the supply was derived entirely from ground-water sources through a system of wells and infiltration galleries located along the south shore of Long Island. This was probably the largest development of its kind in the country. Mr. Goodman's early work in the Bureau was largely in connection with the maintenance and extension of such supplies, he having been in charge of the preparation of plans and specifications and of the construction of new wells and filters. He was responsible also for the planning and construction of a system of high-pressure fire service mains installed in Brooklyn in 1909, and of the three driven well developments and pumping plants within that borough that directly supplied its distribution system. His work at this period included the construction of pumping plants on Long Island, which were required to supply additional water for the Borough of Brooklyn; the operation of these pumping plants (approximately thirty in number); and the maintenance and operation of the high-pressure fire service stations.

---

[1] Memoir prepared by Patrick Quilty, M. Am. Soc. C. E., in collaboration with William Flannery, Chf. Engr., Dept. of Water Supply, Gas and Electricity, City of New York, New York, N. Y., and Tobias Hochlerner, M. Am. Soc. C. E.

In 1910, the position of chief engineer, Borough of Brooklyn, was abolished, and the engineering activities of the entire department were placed under a single chief engineer. In this reorganization, the Division of Investigation, Design and Statistics of the Bureau of Water Supply, an adjunct to the office of the chief engineer, was established with Mr. Goodman in charge.

The functions of the division were sufficiently broad in scope to cover the entire field of water supply engineering. They included the preparation of plans, specifications, contracts, etc., for all water-main extensions and improvements to the distribution system in all boroughs, and for well plants, purification works, buildings, and miscellaneous structures, as well as the installation of mechanical equipment; also investigations of all kinds pertaining to the maintenance, operation, and extension of the system. These also included studies of the adequacy of plants of the several private water companies then operating within city limits, many of which were subsequently acquired by the city, there being only two remaining companies operating in 1941. Mr. Goodman had charge of, and personally performed, a large amount of work in connection with the appraisal of these plants for their acquisition by the City of New York. He also had an important part in determining the rates to be paid these companies for fire protection in the form of hydrant rental, and developed special methods of procedure for the solution of the problems involved.

The work of his division also included the compilation of statistical data relating to rainfall and runoff in the watersheds, the consumption of water, etc., such data being the basis for determining the most advantageous and economical operation of the combined systems of the city's supply and for estimates of the anticipated needs of water in the immediate future.

Following a vacancy that occurred on February 10, 1933, Mr. Goodman was appointed acting deputy chief engineer and, on February 1, 1934, deputy chief engineer of the Bureau of Water Supply. On June 1, 1934, he was appointed acting chief engineer and on May 26, 1936, chief engineer of the Bureau, taking complete charge of the maintenance, operation, and extension of the water supply system. Thus, after thirty-five years of service, he had risen from the lowest ranks to the highest technical position in the Department, but it was not long before he was called to even higher administrative duties. On September 17, 1936, Mayor Fiorello H. LaGuardia designated Mr. Goodman as acting commissioner and, on October 27, 1936, he was appointed by the Mayor as commissioner of the Department of Water Supply, Gas and Electricity.

The ceremony at which he was sworn in to his new office by the Mayor on that date, at the City Hall, was witnessed by a large gathering of distinguished engineers, public officials, and Department employees. The Mayor then stated that the appointment of Mr. Goodman was one which was out of the ordinary, being in conformity with the new city government policy of placing at the head of certain departments Civil Service career men who had long been connected with these departments and had acquired specialized knowledge to fill the positions, such appointments being without regard to political standing or affiliations of the appointees. He noted that Mr. Goodman had devoted his life to city service in the Water Department, thus making him an ideal or "No. 1 career man," and he was frequently so referred to thereafter.

The appointment was singularly opportune and fortunate for the city because of the water supply situation then prevailing. It was one of those critical periods of impending water shortage that have occurred at intervals during the city's growth, the demand on the system having about reached the limit of the dependable supply of the existing sources, and a project to provide an additional supply had just been initiated. This project, involving the construction of the Delaware Aqueduct and the development of the watersheds of the upper Rondout Creek, the Neversink River, and the East Branch of the Delaware River, is now (1941) well under way, but the delivery of the first installment from these new sources is not expected until 1945. There was, therefore, particular need for an engineer having Mr. Goodman's long experience in and knowledge of the water system to head the Department. He was admirably fitted to take measures to carry on and maintain an adequate supply for the city until the new sources became available.

Despite onerous duties in the administration of the two other bureaus of the Department, Mr. Goodman devoted much time to the engineering activities of the Bureau of Water Supply and the operation of the system. An active program was undertaken for the installation of new facilities to pump Croton water within the city and for improvements in the Long Island watershed, so as to enable these sources to be utilized to the fullest possible extent. Commissioner Goodman also initiated an application to the State Water Power and Control Commission for permission to drive new wells to secure an additional supply of 50 mgd in Nassau County, such supply to be developed, if and as it might be needed, before 1945.

The water supply situation was rendered still more serious by the severe drought that began in May, 1939, and continued into March, 1940, being relieved then by heavy rains. During this dry period, the impounding reservoirs, which were full in April, 1939, were steadily depleted so that their contents were only about 40% of their capacity in March, 1940. In this situation, Commissioner Goodman was in active charge of a publicity campaign for the reduction of consumption and the conservation of the supply, this being carried on in the press, over the radio, in the schools, and by notices placed in the subways, hotels, etc. The use of water for flushing and sprinkling streets was temporarily prohibited by the Commissioner.

The results of this campaign of conservation and the measures taken to reduce the demand on the system were very gratifying, the consumption of water in the early months of 1940 being reduced by about as much as 120 mgd, as compared with the same months of 1939. The effects were evident throughout 1940 during which the consumption, within the municipal system, averaged 862 mgd, as against 938 mgd in 1939.

In addition to his many other duties, Commissioner Goodman also was occupied with problems relating to the defense situation, having been appointed a member of Mayor LaGuardia's City Defense Council. His first concern in this matter was to take steps to provide for guarding the system and to make arrangements, in cooperation with the Board of Water Supply, for a force to patrol the watersheds and aqueducts. He was instrumental in having the Governor of the State of New York declare an emergency, as a result of which some 20,000 permits hitherto issued for fishing and boating on the reservoirs were rescinded. A comparatively small number of such permits were re-issued under new regulations, which restricted the areas for these activities.

In the administration of the Bureau of Gas and Electricity, Commissioner Goodman also effected substantial savings in the cost of the lighting of streets and public buildings, these services being provided under contracts with private utilities.

Commissioner Goodman, although of slight physique, was an indefatigable worker. He underwent a severe operation in June, 1940, and retired on July 8 of that year in the belief that his usefulness would be impaired to such an extent that he could not continue his many duties as commissioner. However, he was reappointed by the Mayor and, as soon as his health improved, he returned to service, continuing active almost until his death.

His long service was always marked by intense loyalty and devotion to the interests of the city, and he endeavored to imbue and inspire his subordinates and associates with the same objectives. He was held in high esteem and affection by all of the personnel and never failed to attend any gathering, whether social or professional, of Department employees so as to obtain more intimate contact with them and become personally acquainted with as many of the 3,000 employees as possible. Commissioner Goodman's name will be added to those of the many distinguished engineers and administrators who have been engaged on the construction and operation of New York City's vast water supply system since its inception more than one hundred years ago.

In addition to his membership in the Society, he was also for many years a member of the American Water Works Association and the Municipal Engineers of the City of New York.

On June 28, 1916, he was married to Dorothy Goldberger of Perth Amboy, N. J., who survives him. Their only son, Lawrence Eugene Goodman, Jun. Am. Soc. C. E., is following his father's profession, having graduated from the Columbia School of Engineering with the degree of Civil Engineer in 1939. Mr. Goodman is also survived by a sister, Mrs. Rose Glucksman; and two brothers, Louis Goodman, Assoc. M. Am. Soc. C. E., and George Goodman.

Mr. Goodman was elected an Associate Member of the American Society of Civil Engineers on June 6, 1906, and a Member on October 10, 1916. He became a Life Member in 1941.

CHARLES SAMUEL GREEN, M. Am. Soc. C. E.[1]

Died October 23, 1941

Charles Samuel Green was born in Toomsboro, Ga., on July 4, 1873, the son of Samuel Gartensteig and Esther (Green) Gartensteig, later Weiss. In 1918 he changed his name to Green, adopting his mother's maiden name.

As a young child, he moved to New York, N. Y., with his family. He was a graduate of the New York City public schools, the College of the City of New York (which he entered at the age of fourteen), and Columbia University, School of Mines, in New York City. In 1891 he received the degree of Bachelor of Science from the College of the City of New York and in 1895 the degree of Civil Engineer from Columbia University.

Upon his graduation from the latter university in 1895, he was appointed assistant engineer of the Long Island Railroad Company, Montauk Division, and put in charge of field party on location and construction. From 1895 to 1896 he was assistant in the office of the late William Barclay Parsons,[2] Hon. M. Am. Soc. C. E., on design of the first rapid transit subway for New York City.

In 1896 Mr. Green became assistant engineer, Bureau of Sewers, Borough of The Bronx, New York City, in charge of construction of sewers, including the contract for the Broadway sewer (approximate cost, $1,000,000). He held this position until 1902, when he became assistant engineer, Bureau of Highways, Borough of The Bronx, in charge of numerous contracts for grading and paving streets and of design and construction of bridges and viaducts of steel, masonry, and reinforced concrete. From 1910 to 1918 he was engineer of design, Office of the President of the Borough of The Bronx, in charge of design and preparation of plans and contracts for all improvements under the jurisdiction of the President of the Borough, including paving, bridges, viaducts, walls, culverts, etc. (approximate cost, $3,000,000 during 1911). He was also at various times construction engineer and designer of foundations and steel frames for buildings.

In 1918, during the World War, he was commissioned a Captain in the Engineer Corps of the United States Army. He served overseas in France in 1918 and 1919 as acting Major in command of a labor battalion of engineers.

Mr. Green was a member of the Harmonie and City Athletic Clubs of New York for several years. He was a charter member of Fairview Country Club, serving as president, governor, and for many years chairman of the Green Committee. In the latter capacity he laid out and built three different golf courses.

At the time of his death he was in private practice as a consulting engineer, with an office at 119 West 57th Street, New York City. He was an expert at drawing difficult specifications and contracts and was a master in the use of correct, terse English. His letters and contracts were models of comprehensive brevity.

---

[1] Memoir prepared by Charles Griffith Moses, New York, N. Y.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 98 (1933), p. 1485.

During the last few years of his life he devoted much time to the instruction in English, and Americanization, of European war refugees, chiefly professional men. He not only taught a considerable number of German, Austrian, and Italian engineers colloquial English and American practices, but was remarkably successful in instilling in these foreign, professional contemporaries, many of whom were past middle age, the fine ideals of democracy and constitutional government so dear to his heart.

Mr. Green was never married. All his life he was deeply interested in religious, ethical, charitable, and educational matters and cheerfully shared with others his wealth of wisdom, good judgment, and kindliness. His keen sense of humor and his remarkable fund of general information made him outstanding and popular with his host of friends. He was an ardent fisherman and golfer.

Mr. Green was elected a Junior of the American Society of Civil Engineers on October 6, 1896; an Associate Member on May 6, 1903; and a Member on April 30, 1912.

JOHN LYLE HARRINGTON, M. Am. Soc. C. E.[1]

DIED MAY 20, 1942

John Lyle Harrington was born on December 7, 1868, at Lawrence, Kans., the son of Robert Charles and Angeline Virginia (Henry) Harrington. During most of his youth, the family lived on their homestead near De Sota, about 15 miles east of Lawrence. His early schooling was very irregular, as was most often the case with the boys on Kansas farms in those days. He entered the University of Kansas, at Lawrence (by passing entrance examinations), with a total of only about four years attendance at grade and secondary schools. He was graduated from the University in 1895 with the three degrees of Bachelor of Arts, Bachelor of Science, and Civil Engineer. He found time, also, for a large amount of extra reading and for at least the normal participation in student affairs and the social life of the University. He was a member of Sigma Nu fraternity.

His intense desire for knowledge is evidenced by the record of his experience in the twelve years from 1895 to 1907, and he often said of those years that, when he had lost the interest of learning something new in one job, he began to look for another. During two summer vacations, and from June, 1895, to March, 1896, he was in the employ of the late J. A. L. Waddell, Hon. M. Am. Soc. C. E., consulting engineer, at Kansas City, Mo. He then held various positions, as follows: March to August, 1896, in the drafting room of the Elmira Bridge Company at Elmira, N. Y.; August, 1896, to July, 1897, with the Pencoyd Iron Works at Philadelphia, Pa., in charge of work in the drafting room; July, 1897, to January, 1898, with the Keystone Bridge Works of the Carnegie Steel Company at Pittsburgh, Pa., in charge of preparation of general and detail plans for numerous bridges, including various bridges and viaducts for the Union Railroad approach to the Pittsburgh and Lake Erie Railroad bridge over the Ohio River; January to September, 1898, with the Cambria Steel Company at Johnstown, Pa., first as assistant superintendent, Structural Department, designing the structural shops, then in charge of engineering, and later in charge of the shop and structural material yards; September, 1898, to March, 1899, with the Bucyrus Company at South Milwaukee, Wis., as assistant chief engineer and assistant superintendent; March to December, 1899, with the Northwestern Elevated Railroad Company in Chicago, Ill., as assistant to the chief engineer, in charge of preparation of shop plans and of inspection of fabrication of steelwork at the shops of the Elmira Bridge Company and Union Bridge Company; December, 1899, to November, 1900, with the Berlin Iron Bridge Company at East Berlin, Conn., as designer; November, 1900, to November, 1901, with the Baltimore and Ohio Railroad Company at Baltimore, Md., as assistant engineer of bridges and buildings; November, 1901, to January, 1905, with the C. W. Hunt Company in New York, N. Y., first in charge of preparation of detail drawings of structural work and of general contract plans for bidding purposes, and later as executive engineer in charge of estimating, contracting, etc.; and January, 1905, to January, 1907, with the Locomotive and Machine Company at Montreal, Quebec, Canada (a subsidiary of the American Locomotive Company), as chief engineer and general manager, having charge of the building and then the operation of its plant.

---

[1] Memoir prepared by Frank M. Cortelyou, M. Am. Soc. C. E., in collaboration with R. P. Woods, E. E. Howard, and O. W. J. Anschuetz, Members, Am. Soc. C. E.

During these twelve years from 1895 to 1907 Mr. Harrington unquestionably always had in mind the definite goal of the independent practice of his profession as a consulting engineer. He chose such a course in preference to accepting an offer of an annual salary of $25,000 to become a vice-president of one of the large railway systems of the United States. Thus began thirty-five years of practice as consulting engineer—from 1907 to 1914 as a partner in Waddell and Harrington, from 1914 to 1928 as senior partner of the firm of Harrington, Howard and Ash, and after 1928 as senior partner of the firm of Harrington and Cortelyou, all specializing in the field of bridge engineering. Some 250 projects were handled by these firms, the services performed being generally the complete engineering work from inception to completion, although at times the services covered only the design of and detail plans for the structure and in rarer cases only consultation work. Their work covered all sections of the United States, numerous structures in Canada, and some in foreign countries, as shown by the following principal projects:

Bridges over the Mississippi River at St. Paul, Minn. (Chicago Great Western Railroad), Keithsburg, Ill., Alton, Ill., Louisiana, Mo., Cape Girardeau, Mo., Vicksburg, Miss., and Baton Rouge, La.; bridges over the Missouri River at Fort Bellefontaine, Mo., Booneville, Mo., Waverly, Mo., Kansas City, Mo., Rulo, Nebr., Blair, Nebr., Yankton, S. Dak., and Mondak, Mont.; bridge over the Ohio River at Paducah, Ky.; seven bridges over the Chesapeake and Delaware Canal in Delaware and Maryland; seventeen bridges over the Welland Ship Canal in Canada; nineteen bridges and viaducts for the Canadian Northern Pacific Railway in British Columbia; three bridges in Vancouver, B. C.; four bridges in Tacoma, Wash.; two bridges in Spokane, Wash.; the Columbia River Bridge between Portland, Ore., and Vancouver, Wash.; four bridges over the Willamette River in Oregon, including the double-deck, vertical lift bridge at Portland; two vertical lift bridges and one bascule bridge over the Sacramento River, the Dumbarton Highway Bridge over San Francisco Bay near Palo Alto, and the concrete arch bridge over Arroyo Seco at Pasadena, all in California; two bridges over the Tombigbee River and one over the Tennessee River, in Alabama, and also the Mobile Bay Bridge at Mobile, Ala.; bridges over the Arkansas River at Van Buren, Morrilton, Little Rock, and Mozart, Ark.; two bridges over the St. Johns River at Jacksonville, Fla., and the Lee Street Viaduct at Jacksonville; nine bridges over the Miami River, all of the bascule type, at Miami, Fla.; the Spring Street Viaduct at Atlanta, Ga.; the vertical lift bridges of the Pennsylvania Railroad over the Chicago and Calumet rivers and that of the Lake Shore and Michigan Southern Railway (later the New York Central System) over the Calumet River at Chicago; Market Street Viaduct at Shreveport, La.; the Louisiana and Arkansas Railway Bridge over the Atchafalaya River (extension on west end) at Simmesport, La.; the vertical lift bridge over the Duluth Ship Channel at Duluth, Minn.; fifteen bridges for Kansas City and Jackson County, Missouri, of which the most important are the 12th Street and 23d Street viaducts; bridges over Great Egg Inlet at Ocean City, over the Cooper River at Camden, and over the Hackensack River at Hackensack, all in New Jersey; the West Third Street Viaduct in Jamestown, N. Y.; the Northhill Viaduct at Akron, Detroit Superior Viaduct at Cleveland, Sandusky Bay Bridge at Sandusky, and eight bridges over the Miami, Mad, and Wolf rivers at Dayton, all in Ohio; the concrete arch bridge over the Colorado River at Congress Avenue, Austin, Tex.; the vertical lift bridge over the Southern Branch of the Elizabeth River at Norfolk, the Wasena Viaduct at Roanoke, and the Ninth Street Bridge at Richmond, all in Virginia; the Piscataqua River Bridge at Portsmouth, N. H.; the Massachusetts Avenue and K Street bridges over Rock Creek and Rock Creek and Potomac Parkway in Washington, D. C.; the Waikato River Bridge at Hamilton, New Zealand; and the Don River Bridge at Rostoff, Russia.

His most outstanding contribution to bridge engineering was in the development of the vertical lift type of movable span. He brought to his partnership with Mr. Waddell a considerable experience in mechanical engineering work, principally gained during his four years with the C. W. Hunt Company. This experience, applied to the operating problems of the vertical lift type of span, resulted in numerous patents for the firm's designs and the construction of twenty-seven vertical lift spans. Two of these are worthy of special mention because of their variation from the usual type. The double-deck railway and highway bridge over the Missouri River at Kansas City has the upper (highway) deck carried by a through, fixed-truss span and the lower deck (double-track railway), over 400 ft long, suspended on vertical hangers and capable of being raised and lowered, the hangers telescoping into the vertical members of the through fixed trusses. The double-deck highway and railway bridge over the Willamette River at Portland has a similar lower deck, but the entire span can also be raised and lowered, the operation of the lower deck relative to the upper being independent of the operation of the whole span. In all, seventy-four vertical lift bridges have been built by Mr. Harrington's firms.

In August, 1932, Mr. Harrington was called to Washington, D. C., by President Herbert Hoover, Hon. M. Am. Soc. C. E., to become a member of the Engineers Advisory Board of the Reconstruction Finance Corporation (RFC) when that agency was formed to aid in combating the 1929–1933 depression. This board dealt with only one phase of the Corporation's activities—the financing of new construction projects. Mr. Harrington had a most prominent part in the organization of the Board's activities and in its work, and he remained with the RFC as chief engineer after the authority to make such loans was transferred to the Public Works Administration. Essentially, his entire time from August, 1932, to January, 1934, was devoted to this service, which he accepted without hesitation as a patriotic duty at considerable financial loss and, as it developed, at material cost to his health. This Board dealt with nearly 700 applications for loans on self-liquidating projects for amounts ranging from a few thousand to over 100 million dollars. Loans were made on approximately one third of the applications and all but one proved profitable, enabling the RFC to dispose later of the securities taken.

Mr. Harrington had a wide range of interests outside of his own immediate business affairs. He was greatly interested in engineering education and gave liberally of his time in addressing engineering students. He was particularly active in the American Society of Mechanical Engineers (A. S. M. E.), serving as vice-president from 1920 to 1922 and as president in 1923. He was a member of the American Engineering Council as representative of the A. S. M. E. from 1926 to 1932. For many years he was on the Board of Trustees of Robert College at Istanbul, Turkey, resigning only a few months before his death. He was a member of the American Railway Engineering Association, the American Society for Testing Materials, the Institution of Civil Engineers (England), The Engineering Institute of Canada, the American Association for the Advancement of Science, and the Newcomen Society. He was a member of Sigma Xi, Tau Beta Pi (president in 1917), and Theta Tau. He received from McGill University, in Montreal, the degree of Bachelor of Science in 1906 and that of Master of Science in 1908. In 1930 he received the honorary degree of Doctor of Engineering from Case School of Applied Science in Cleveland, Ohio.

In Kansas City, which was his home continuously after 1907, he was a member of the University Club, Mission Hills Country Club, and the Engineers Club (its first president in 1911). He was a life member of the German

Hospital Association (later renamed Research Hospital). He was from 1932 to 1941 a member of the Cosmos Club in Washington, D. C.

On June 21, 1899, Mr. Harrington was married to Daisy June Orton of White Cloud, Kans., also a graduate of the University of Kansas. He is survived by her and their only son, Thomas Orton Harrington.

Mr. Harrington had a most forceful character and remarkable energy and ability. His success was not a result of chance but of his own qualities. He had a keen and active mind and the power of memory such as few possess. He was a fluent speaker and writer, but wrote very little for publication. Essentially all the addresses he made were given extemporaneously. He was ever a voluminous reader, and there was no limit to the variety of subject in which he took interest and sought information. The structures which he built are monuments to his memory, but these do not measure his accomplishments through the influence he exerted on the lives of others. Many could say as one has said that "My close personal contacts with him during those five years have always been considered invaluable. Mr. Harrington was one of the most remarkable and capable men I have ever known, and I deeply appreciated his status as one of the outstanding men of our time, both in engineering and without."

Mr. Harrington was elected a Junior of the American Society of Civil Engineers on August 31, 1897; an Associate Member on October 4, 1899; and a Member on December 1, 1903.

BURR POWELL HARRISON, M. Am. Soc. C. E.[1]

Died January 21, 1942

Burr Powell Harrison was born of a family long prominent in Virginia history. His forebears included pre-Revolutionary ancestors who seemed prophetic of life interest in engineering. For instance, the earliest known exploration of the area of Loudoun County, Virginia, where Mr. Harrison lived and died, was made in 1699 by Burr Harrison of Chipawamsic, a lineal ancestor, under the direction of Col. Francis Nicholson, Governor of Virginia. In 1787 Col. Leven Powell, another ancestor, who had raised and fought with the 16th Regiment of Virginia Continentals under Gen. George Washington, laid out the town of Middleburg on the old road running to Ashley's Gap. In addition, there have been distinguished contributors to American colonial and national life, including a member of the Continental Congress, an ambassador to the Court of St. James, Senators, Congressmen, and other men of prominence.

Born on December 7, 1875, Burr Powell Harrison was the son of Capt. Powell Harrison, a prominent lawyer of Leesburg, Va., who had served as a Captain of Cavalry under the Confederate Cavalry leader, Gen. "Jeb" Stuart.

---

[1] Memoir prepared by J. D. Fauntleroy, M. Am. Soc. C. E.

His mother was Janet Fauntleroy, daughter of Capt. Charles Fauntleroy, who during the "War Between the States" commanded the Confederate cruiser *Shenandoah.*

In his early youth Mr. Harrison attended public and private schools in Leesburg. In 1893 he entered Virginia Military Institute at Lexington, Va., as a third classman. He was graduated with the degree of Bachelor of Science in Civil Engineering in 1896 and in 1914 he was awarded the degree of Civil Engineer. For two years he taught in the public schools of Fairfax County, Virginia. He then sought employment as a civil engineer. At that time work of such nature was scarce in Virginia, so he accepted employment as an instrumentman for the Nicaraguan Canal Commission. He returned to the United States in 1901 and was employed by the Baltimore and Ohio Railroad Company as a transitman. The next year he was made resident engineer, in charge of the construction of 7½ miles of the Quemahoning Branch of the Baltimore and Ohio Railroad in Somerset County, Pennsylvania. Upon completion of this work he was promoted to assistant engineer of the Baltimore and Ohio Railroad Company, in charge of locating parties. He left the employ of this company in 1904 and for a while was employed as engineer for the Filtration Company of America, on the construction of a filtration plant at Washington, D. C. From Washington, D. C., he went to Kansas City, Mo., where he was employed in 1904 and 1905, working up plans for the terminals and the new depot for the United Railroads.

During the years 1905 to 1907 he lived in New York, N. Y., where he was employed by N. R. Chapman and Company and by Halle and Steiglits, Brokers. From 1907 to 1912 he was employed by the U. S. Engineers, first as inspector and then as junior engineer in charge of dredging operations on the Potomac River and of deepening the channel leading to Baltimore, Md.

In 1912 he entered the employ of the Maryland State Roads Commission. One of his duties here was to organize the State Maintenance System, one of the first road maintenance systems in the United States. He remained with the Maryland Roads Commission and received several promotions, becoming first assistant engineer to the chief in 1918. He left the Roads Commission in 1918 and became harbor engineer of Baltimore City. Subsequently, he practiced as a consulting engineer in Baltimore City.

In 1922 he was appointed engineer of location and plans to the State Highway Commission of Virginia. He located the new state highway roads under the "pay-as-you-go" régime inaugurated by Gov. Harry Byrd. He was always a hard worker and never allowed anything to interfere with his duties. His great interest was to eliminate unnecessary curves and bends on highways to make them safe for the traveling public. He also tried to reduce grades, and was one of the first highway engineers to pay close attention to the elevation of curves. Once, when taking part in a discussion among a gathering of engineers, he was asked what, in his opinion, was the best type of road surface, and he replied: "The most important feature on any highway is its location. Any type you may select will wear out, but the location is permanent." Visiting engineers often praise the beautiful locations of the state highways of Virginia. They stand as a living testimonial to his skill and wisdom.

Mr. Harrison was nicknamed "Long Tangent" at the Virginia Highway Department. The chiefs of fifteen survey parties presented him with a gold Hamilton watch and gold chain, in token of their appreciation and affection. Inscribed on the inside of the watch was: "B. P. Harrison, Locating Engineer, a token of appreciation from the Locating Parties, 1927."

He left the State Highway Department in August, 1930, and entered the U. S. Bureau of Public Roads, where he had charge of the economic work in the states comprising the 10th Federal Aid District. This necessitated constant intercourse with state and county officials to find out the revenues received by various states, counties, and subdivisions, the sources from which these funds were derived, and the purposes for which they were expended and the results obtained. He was generally well liked by all with whom he came in contact. His services in the Bureau were so satisfactory that he received several promotions, the last only a short time before his death.

Mr. Harrison was proud of his birth and lineage and was always dignified and courteous in his bearings. He was a devoted husband and father. It has been commented on by several engineers who have traveled with him over Virginia that, no matter how far he had driven that day and notwithstanding how hard he had worked, he always found time at night to call his wife by long distance telephone and to inquire about her and the family.

He was a fine conversationalist, and for his friends it was always a pleasure to hear him tell about his varied experiences and how he had solved various complex problems that had arisen in his work. He was a Christian and a member of St. James Episcopal Church in Leesburg. He never used profane language.

In 1910 he was married to Louise Goldsborough, who came from a family long prominent on the eastern shore of Maryland. Her father, Dr. Brice Worthington Goldsborough, was a very prominent and much beloved surgeon and physician. Mr. Harrison is survived by his widow; a son, Burr Powell Harrison, Jr., a Captain in the U. S. Army; three daughters, Louise Dulin (Mrs. Francis Landey Patton), Nannie (Mrs. James S. Cox), and Lalla Fauntleroy Harrison; five grandchildren, Anna Harrison Cox, James S. Cox, Jr., Brice Goldsborough Cox, Louise Goldsborough Patton, and Francis Landey Patton IV; a brother, Charles Fauntleroy Harrison; and three sisters, Mrs. E. B. White, Mrs. Henry Lynn, and Mrs. Walter H. Taylor.

Mr. Harrison was elected a Member of the American Society of Civil Engineers on October 3, 1911.

GEORGE WILLIAM HAWLEY, M. Am. Soc. C. E.[1]

DIED MARCH 17, 1942

The happy smile and gracious, cheerful greeting known to his fellow workers in the office of the state engineer for more than twelve years was erased and stilled forever at 6:00 p.m. on March 17, 1942. The end came less than twenty-four hours after George Hawley had gone to the hospital for a check-up of a heart ailment of some years' standing.

---

[1] Memoir prepared by Edward Hyatt and W. A. Perkins, Members, Am. Soc. C. E., and Emerson Dolliver, Assoc. M. Am. Soc. C. E.

George William Hawley, the son of James and Margaret Hawley, and the eldest of three children, was born at Portland, Ore., on November 19, 1889. He acquired his elementary and preparatory education in the schools of Portland and entered Stanford University (California) in the fall of 1909. He received the degree of Bachelor of Science in Civil Engineering in 1913 and the degree of Civil Engineer in 1916. Because of his scientific achievements, he was elected a member of Sigma Xi.

After his graduation, his entire life was spent in the pursuit of his chosen profession. His first engagement was with the Oregon Electric Company, which he left in 1914 to become construction engineer with the South San Joaquin Irrigation District. His principal work for the District was as engineer in charge of the construction of Woodward Dam, a large semi-hydraulic fill. He severed this connection in 1917 to enter the employ of the East Bay Water Company, where he rose to the position of chief construction engineer. Two major projects were completed under his régime—the later stages of San Pablo Dam and the construction of Upper San Leandro Dam, both large hydraulic-fill dams. These were in addition to the regular construction program of a large domestic water system. He remained in this position until the company was sold to the East Bay Municipal Utility District in 1928, when he became assistant director of operations for that organization. From 1925 until the latter part of 1929, he also maintained a private practice as consulting engineer on hydraulic projects.

In September, 1929, following an enactment by the Legislature placing all dams in the State of California under the jurisdiction of the state engineer, Mr. Hawley was appointed deputy state engineer in direct charge of construction, maintenance, and repair of more than 800 dams in the state. Through later amendment, more than 200 small-sized dams were removed from the list, and at the end of his régime the number under his supervision was 639. The duties of the office called for travel to all parts of the state and contact with all the hydraulic engineers and operators of all types of water projects in which dams were involved. Under his able direction, the Dam Department of the State Division of Water Resources became a highly efficient organization that had the full confidence of the general public and such federal agencies as the U. S. Forest Service and the Federal Power Commission, with which it had frequent and close contact.

On March 7, 1916, Mr. Hawley was married to Sara Nancy Williams of Portland, Ore., who survives him. Also surviving are a brother, Henry James Hawley, and a sister, Mary E. Hawley. Mr. and Mrs. Hawley were most welcome attendants at most of the engineering gatherings held on the Pacific Coast for many years.

One of George Hawley's outstanding characteristics was his kindly and gentlemanly demeanor, whether in the presence of acquaintances, superiors, associates, or subordinates. His example of loyalty to his superiors, fidelity to his job, and keen-mindedness and alertness to protect the interests of the state could well be emulated by all.

Because of his wide technical interest he held membership in the American Concrete Institute (serving as a member of the Committee on Properties of Mass Concrete), the American Geophysical Union, and the American Water Works Association. He served as a member of several committees of the Society, the more important of which were the Special Committee on Irrigation Hydraulics, and the Subcommittee on Structural Design of Embankments and Foundations of the Committee on Earth Dams and Embankments.

Mr. Hawley was elected a Junior of the American Society of Civil Engineers on September 2, 1914; an Associate Member on May 13, 1918; and a Member on January 14, 1929.

EDWARD ADOLPH HERMANN, M. Am. Soc. C. E.[1]

Died June 12, 1941

Edward Adolph Hermann was born at Hermannsburg, Washington County, Ark., on December 28, 1856. He was the son of Charles F. Hermann and Caroline (Wilhelmi) Hermann, who had come to the United States from Germany. With a relative, they founded the town of Hermannsburg, where they maintained a store and a flour mill.

During the Civil War the country was terrorized by guerrillas who robbed and murdered adherents to both sides impartially. When a Union column came through this district, the Hermann family moved to St. Louis, Mo., which was Edward A. Hermann's home most of his life.

Mr. Hermann attended the public schools in St. Louis, and in 1879 was graduated in Civil Engineering from Rensselaer Polytechnic Institute at Troy, N. Y. His early career was as follows: Draftsman in the office of M. E. C. Darly, mechanical engineer, at St. Louis, from July, 1879, to October, 1879; assistant engineer, Grand Tower Mining, Manufacturing and Transportation Company at Grand Tower, Ill., from October, 1879, to January, 1880; draftsman in Bridges Department of city engineer's office of St. Louis from January, 1880, to May, 1880; draftsman with Atlantic Refining Company of Philadelphia, Pa., from May, 1880, to July, 1880; assistant engineer, Lake Erie and Western Railroad Company, at LaFayette, Ind., from July, 1880, to October, 1881; assistant engineer, Pennsylvania Railroad Company (Pittsburgh, Fort Wayne and Chicago Railway Company and branches), from October, 1881, to April, 1882, in charge of improvements for third and fourth main tracks between Allegheny, Pa., and Dixmont, Pa., a distance of ten miles; and April, 1882, to January, 1887, assistant engineer, Cincinnati, Indianapolis, St. Louis and Chicago Railway Company (later part of Cleveland, Cincinnati, Chicago and St. Louis Railway Company [Big Four]). While with the latter company, Mr. Hermann was in charge of construction of changes in alinement of main track at several places, extension of second main track, building of several short branch lines, erection of wooden and iron bridges, and construction of piers, abutments, yards, and depots. About this time he wrote "Steam Shovels and Steam Shovel Work,"[2] which was the first book written on this subject.

---

[1] Memoir prepared by C. E. Hermann, Pres., Reliance Whiting Co., Alton, Ill.

In 1899 he resigned from his position as assistant chief engineer of the Big Four Railroad Company and became sewer commissioner and member of the old Board of Improvements in St. Louis. He took an active part in the work of the Board and served on many of its committees assigned to the practical working out of plans. He was particularly active in compelling the street railways to use power brakes on their cars, and was an expert on this subject, due to his long experience on steam railroads.

After serving his term of four years as sewer commissioner, he declined reappointment, and in 1904 bought a small quarry at Alton, Ill., which he incorporated under the name of Reliance Quarry and Construction Company. This plant grew considerably under his management. The quarry contains a large quantity of high calcium rock suitable for the manufacture of pulverized limestone for domestic whiting. In 1919 a pulverizing plant was added, and the company was reincorporated as the Reliance Whiting Company. This company has continued in operation ever since and was Mr. Hermann's chief interest. He was active in its management, and continued in good health until his sudden death from a cerebral hemorrhage on June 12, 1941.

Mr. Hermann was liked and respected by the entire business community in Alton, and had a great many friends. His chief interests outside of his business were his family, his books, and his activities in the engineering profession generally.

He was married to Florence Pitzman at St. Louis on April 30, 1896, and is survived by his widow and a son, Charles Edward Hermann, who succeeded him as president of the Reliance Whiting Company.

Mr. Hermann was elected a Member of the American Society of Civil Engineers on April 6, 1887.

BENJAMIN ALEXANDER HODGDON, M. Am. Soc. C. E.[1]

DIED APRIL 6, 1941

Benjamin Alexander Hodgdon was born at Tremont, Mount Desert Island, Me., on September 6, 1875, the son of Benjamin E. and Mary (Beverly) Hodgdon. He was a descendant of Nicholas Hodgdon who came from Herfordshire, England, and settled in Hingham, Mass., in 1635. His great-grandfather, Joseph Hodgdon, enlisted in the Continental Army from Scarboro, Me., and at the close of the Revolutionary War took up a grant of land on

---

[2] "Steam Shovels and Steam Shovel Work," by Edward Adolph Hermann, Engineering News Publishing Co., New York, N. Y., 1894.

[1] Memoir prepared by Alfred M. Wyman and John H. Myers, Members, Am. Soc. C. E.

Mount Desert Island, where his descendants continue to live. His father, following the traditions of the family, was owner and captain of one of the fleet of New England schooners that have now disappeared from the sea.

When Benjamin Hodgdon was still a young boy, his father was forced to retire from active service at sea because of ill health, and the family moved to Somerville, Mass. Mr. Hodgdon was educated in the public schools of Somerville and Boston, Mass., and was graduated from the Massachusetts Nautical Training School, at Boston, in 1897 after a cruise to England and the Mediterranean Sea, during which he held the rank of cadet captain.

His first engineering engagements consisted of various assignments in the vicinity of Boston. They included surveys for parts of the original Metropolitan Park System, construction of the Boston Elevated Railway, and work as inspector and transitman at the Boston Navy Yard. These assignments were interspersed with sea trips as deck officer on steamships sailing from Boston to South America, the West Indies, and New York, N. Y. He held a commission as Lieutenant (junior grade) in the Massachusetts Naval Reserve.

In September, 1904, Mr. Hodgdon joined the engineering force of the New York City Rapid Transit Railroad Commission as assistant engineer. He was employed continuously from that time until his retirement in 1938 on subway construction with that Commission and its successors. As section engineer he was in immediate charge of several of the more difficult parts of the subway construction work, now forgotten, since, unlike many of the more spectacular structures of engineers, they function out of view beneath the highways of a great city.

Between 1904 and 1907 Mr. Hodgdon was serving his apprenticeship in subway construction. Between May of the latter year and November, 1909, he was chief of party on the construction of part of the so-called Center Street Loop, which connects the Williamsburgh and Manhattan bridges over the East River with the Whitehall Street Tunnel beneath it. After an assignment to office work, he was connected, between February, 1911, and July, 1929, with another part of this loop as chief of party and as section engineer. During the period from July, 1912, to May, 1917, he was section engineer in charge of Section 2A of Route 5 and Section 2 of Route 20. These were the official names of the subways along Broadway from Walker to Howard streets and on Canal Street between Broadway and the Bowery. The latter section included a terminal station connected by passageways with the subway along Broadway. Owing to the high elevation of ground water, this was a difficult piece of construction. It was necessary to underpin several buildings and the existing subway on Lafayette Street.

Following this work, Mr. Hodgdon was in charge of the building of Section 5 of Routes 4 and 36, which was the subway under 59th and 60th streets from Seventh to Second avenues. From January, 1919, until May, 1925, he was assigned to the Track Division and during this period was in charge of laying the tracks in the 180th Street and the Jerome Avenue yards, and also superintended the laying of the tracks in the 60th Street Tunnel under the East River.

In May, 1925, he returned to construction work and until February, 1928, was in charge of the work of building a section of the four-track subway in a deep rock excavation along Central Park West from 79th to 89th streets. This work was officially known as Section 1A of Route 78 and was part of the Independent System. From February, 1928, to December, 1930, Mr. Hodgdon was in charge of construction of another section of the Independent System. It was officially known as Section 5 of Route 101 and extended along Greenwich and Sixth avenues from Bank Street to West 3d Street. The work included the underpinning of buildings and the column foundations of the Sixth Avenue elevated railroad. The material encountered in the excavation was water bearing and unstable. In the latter part of 1930 and the early part of 1931, Mr. Hodgdon took charge of the construction of a passageway leading from the subway on Eighth Avenue through 41st Street to the subway on Seventh Avenue. Following this he assisted in the preparation of data for the defense of legal actions that arose out of certain of the subway contracts. On this latter work he was engaged until his retirement in 1938.

After retirement he busied himself about his home, in which he took great pride. Both before and after retirement he often went in summer to his native isle of Mt. Desert, where he could enjoy his hobby of sailing, of which he never tired.

Always conscious of his responsibility, Benjamin Hodgdon was conservative in his judgments, hard working, and ever faithful to his high ideals. He supervised for the City of New York the construction of underground railroads amounting in value to more than $20,000,000.

Mr. Hodgdon was married in June, 1906, to Margaret A. Magee of Newburgh, N. Y. He is survived by his widow and two daughters, Sally Beverly (Mrs. Richard G. Dubraska), and Frances Wilson (Mrs. Paul A. Danielson, Jr.).

As a boy, his summer vacations were often spent at sea with his father and uncle and, in keeping with his nautical background, his principal pastime was sailing. He was known to his friends as the "Skipper," a title that he acquired on week-end yachting trips "down the harbor" with his associates in Boston. His assistants on his work used the same title in addressing him but always with the utmost respect.

His genial disposition, frankness, and old-fashioned honesty, coupled with a keen sense of humor and a homely philosophy, endeared him to his friends, who included almost every one with whom he came in contact.

He was a member of the Ridgeview Congregational Church of White Plains, N. Y.

Mr. Hodgdon was elected an Associate Member of the American Society of Civil Engineers on March 2, 1909, and a Member on January 14, 1919.

HOWARD CECIL LEE HUMPHREYS, M. Am. Soc. C. E.[1]

DIED JULY 18, 1941

Howard Cecil Lee Humphreys (known as Cecil Lee Howard Humphreys) was born at Wembley, Middlesex, England, on September 7, 1893. His parents were Henry Howard Humphreys and Alice (Page Tazer) Humphreys. He was educated at Burford Grammar School and Westminster School, London, England, which he left in 1911 to join his father who was then conducting a consulting civil engineering practice in Westminster, London. Mr. Humphreys' period of pupilage lasted from 1911 to 1914, during which time he was engaged upon the construction of a reservoir for the Letchworth Garden City Company in Hertfordshire and on surveys and the preparation of drawings for a number of water and drainage projects for which his father was the engineer.

At the outbreak of the World War in 1914, Mr. Humphreys was among the foremost of those who volunteered for military service and, within a few days, his life had changed completely from that of an engineer engaged upon the preparation of schemes for the betterment of living conditions to that of a soldier in the Honourable Artillery Company. After a few weeks of training he was sent to France where he served for some months; he returned to England on leave and became acutely ill with trench fever. On his recovery he was granted a commission in the 17th London Regiment, and he again saw service in France and later in Salonika (Greece) and Palestine. He was in France when the war ended.

In 1919 he was demobilized and rejoined his father's practice which was then beginning to recover from the stagnation of the war period. The struggle was a difficult one, for Britain's economic situation was bad, prices were high, and the cry for curtailment of expenditure was insistent. Contractors who had become accustomed to the free and easy percentage-on-cost war contracts were reluctant to give firm-priced bids, and it was for a time almost impossible to let contracts. Gradually conditions improved, but some years elapsed before they began to approach normal. Much faith and perseverance were required in this difficult period, but Mr. Humphreys never gave up hope and, in the end, he was rewarded. In 1925 he was made a partner, and public works by then were being undertaken freely.

In 1930 Mr. Humphreys' father died, and he became senior partner of the firm of Howard Humphreys and Sons. The severe economic crisis of 1930–1933 soon afterward descended upon Britain, and public works were curtailed or stopped in so far as possible. A dreary period of partial inaction followed, during which the engineering profession suffered the greatest possible hardships. Once again, however, conditions became better, and from 1933 to 1939 public works were undertaken in ever-increasing volume with the result that, by the time of the outbreak of war in 1939, Mr. Humphreys' firm had a very large volume of work in hand. This work comprised projects for roads, bridges, water supply, and drainage in England and for water supply and drainage in the British colonies. A particularly interesting English scheme was the improvement of the London-Holyhead (Wales) road at Penmaenmawr and at Penyclip, described in a paper written by Mr. Humphreys and delivered at the Institution of Civil Engineers on April 6, 1937.[2] A colonial scheme of equal interest was that of the main drainage of Georgetown, British Guiana, described in a paper delivered at the Institution of Civil Engineers on April 4, 1933.[3]

---

[1] Memoir prepared by G. Howard Humphreys, London, England.

Mr. Humphreys had maintained his connection with the Territorial Army from 1919 onward, and soon after the outbreak of war in 1939 he found himself again in France; by this time he held the rank of Lieutenant-Colonel. He was in the fighting in Belgium, was evacuated from Dunkirk, France, and received the Military Order of the British Empire for "distinguished services in the field." On his return to England he was appointed Chief Signal Officer to the 3d Corps. Late in 1940 he was offered and accepted the post of Director of Works at the Ministry of Works and Buildings, an appointment that gave the greatest satisfaction to all those who knew him. He retired from the Army with the rank of Colonel. His health unfortunately began to fail and at Whitsun, 1941, it was patent that he was dangerously ill.

Colonel Humphreys was a member of the Council of the Institution of Civil Engineers, the Committee of the Association of Consulting Engineers, the Institution of Mechanical Engineers, the Institution of Water Engineers, the Société des Ingénieurs Civils de France, and the Westminster City Council. He was a Freemason and belonged to the Bath and Union clubs.

During his wide and varied experience Colonel Humphreys frequently was called upon to give expert evidence for which he had a special aptitude. He also functioned as an arbitrator on many occasions, and acquired a reputation for his fearless findings and for the manner in which he refused to allow extraneous matters to be brought into dispute so as to cloud the issue.

His personality was one of genial charm coupled with a great sense of humor and an exceptionally generous outlook on life. He enjoyed living and was never more happy than when every moment was fully occupied. His mind worked at high speed, and he generally outstripped any one who was collaborating with him on a problem. He was an ardent advocate of the strictest adherence both to the letter and to the spirit of professional etiquette, and his early death has removed an influence for the best from the British engineering profession. With a view to dispersing misunderstandings as to the professional status of an engineer, Colonel Humphreys, in conjunction with his brother, wrote a book entitled *The Training of a Civil Engineer* in 1932.

---

[2] "The Reconstruction of the Chester-Holyhead Road near Penmaenmawr, North Wales," *Journal,* Inst. C. E., Vol. 6, 1936–1937.

[3] "The Main Drainage of Georgetown, British Guiana," *Proceedings,* Inst. C. E., Vol. 236, May, 1934.

In 1917 he was married to Ailsa Yoxall, the elder daughter of the late Sir James Yoxall, M.P. He is survived by his widow; a daughter, Barbara; and a brother, Guy Howard Humphreys.

Colonel Humphreys was elected a Member of the American Society of Civil Engineers on February 23, 1932.

MURRAY LEE HUTTON, M. Am. Soc. C. E.[1]

Died February 18, 1941

Murray Lee Hutton was born in Washington County, Iowa, on February 11, 1886, the son of Robert and Elizabeth (Duncan) Hutton. He received his early education in the public schools of the county, and was graduated from the Columbus Junction High School in 1904. He was a student in the Civil Engineering Department of Iowa State College, at Ames, for three years and would have been graduated with the Class of 1910 had he completed his college course. He left school at the end of his Junior year, however, to engage in the practice of engineering.

As an engineering student, and later as a practicing engineer, Mr. Hutton's work was always of the intensive, result-producing variety. He had a rare capacity for concentrating on and finishing the task at hand, whether it was a pleasant or distasteful one. Meticulously honest in his thinking as well as in his every act, his reports and recommendations came to be accepted by those who knew him as representing the most complete and accurate information currently available on the subject under consideration.

His ability as a county engineer was early recognized by the Iowa State Highway Commission, with the result that he was offered a position with that organization. As assistant engineer in the Administration Department, he handled most of the details incident to the federal-aid construction program, as well as a wide variety of miscellaneous assignments.

One of the miscellaneous assignments was that of dealing with railroad companies with regard to grade separation and elimination projects. Since at that time there were no special funds for this class of work, such as have since been made available, and since there are no state laws in Iowa that specify a division of costs on projects of this kind, each project was subject to specific negotiations and agreement with the affected railroad. Mr. Hutton made extensive studies and did much research work to determine a fair and equitable division of the cost of each project as between the public and the railroads. As a result of his efforts along this line, agreements were negotiated with railroad companies that resulted in the separation or elimination of many dangerous railway grade crossings.

---

[1] Memoir prepared by W. H. Root, Assoc. M. Am. Soc. C. E., and C. Coykendall, M. Am. Soc. C. E.

Another one of the miscellaneous assignments handled by Mr. Hutton while he was assistant administration engineer for the State Highway Commission was the supervision of much of the engineering work that the Commission did for the State Board of Conservation. Through his association with this work he developed a keen interest in the state's conservation program. As a result of contacts made in this work, in 1929 he was offered, and accepted, the position of chief engineer of the Iowa State Board of Conservation. In 1935 he became director of State Conservation and held this position until his death.

Mr. Hutton will be long and gratefully remembered by the people of Iowa for his work in connection with the state's conservation program. To this work he devoted the energy and ability that had always characterized his efforts in his professional work. He familiarized himself with the conservation programs being conducted throughout the United States, and from the knowledge thus gained he formulated the program best suited, in his judgment, to the needs of Iowa. He was a vigorous champion of sound, prudent, forward-looking public administration. He visualized for Iowa a system of state parks so located as to be of easy access to all of the people of the state, and so developed as to afford wholesome and diversified recreation for all—streams and lakes freed from contamination and pollution and abundantly stocked with fish; and a game conservation and propagation program that would again make open hunting seasons possible. Definite and encouraging progress is being made toward all of these goals.

Mr. Hutton was an associate member of the Iowa Academy of Science, and a member of the Association of Midwest Fish and Game Commissioners. He served as president of the latter in 1940. Among his writings were: "Proposed Work in Louisa County for the Coming Year" (*The Iowa Engineer,* 14: 111–11, 1913); "Engineering Phases of Conservation," Associated State Engineering Societies (*Bulletin 8,* No. 4: 40–7, October, 1933); "Upstream Reservoirs" (*American Wildlife,* May–June, 1937). He also made a statement for the Association of Midwest Fish and Game Commissioners to the Joint Congressional Committee in Forestry at its hearing in Madison, Wis., on December 18 and 19, 1939, before the Select Commission on Conservation of Wildlife resources (House of Representatives 76th Congress, 3d Session, Pursuant H. Session 64, 1940: 73–81).

That Mr. Hutton's program and leadership in the conservation field met with public approval is best shown by the fact that he was retained in office through changing state administrations. Numerous changes were made in the personnel of the State Board of Conservation, but Mr. Hutton continued as the executive officer of the organization. To know him was to have high respect for his ability and complete confidence in his integrity and sincerity. His untimely death is a personal loss to his many friends, a public loss to the conservation program in Iowa and the Nation, and a professional loss to the civil engineering fraternity.

On April 25, 1913, he was married to Tecla Johnson in Pocatello, Idaho. He is survived by his widow and a son, Donald W. Hutton.

Mr. Hutton was elected an Associate Member of the American Society of Civil Engineers on June 23, 1916, and a Member on April 17, 1923.

FRANK CALEB KELTON, M. Am. Soc. C. E.[1]

DIED FEBRUARY 25, 1942

Frank Caleb Kelton was born in Montgomery, Vt., on November 25, 1881. He was the son of Judge Otis N. Kelton and Harriet (Clapp) Kelton.

Having a desire to participate in the development of the West, after two years at the University of Vermont, at Burlington, and at the instigation of G. E. P. Smith, M. Am. Soc. C. E., he went to Tucson, Ariz., in 1901, where he entered the University of Arizona from which he was graduated in June, 1904, with the degree of Bachelor of Science. He later attended the University of California, in Berkeley, where he received the degree of Master of Science in June, 1916.

Mr. Kelton engaged in private survey work in Tucson in 1904 and 1905 and thereafter was with the engineering staffs of the Gila Valley, Globe, and Northern Railroad Company, in Arizona, as draftsman and computer, and the Ferrocarril de Cananea Rio Yaqui and Pacifico companies, in Sonora, Mexico, on railroad construction. In January, 1907, he became associated with the Agricultural Experiment Station of the University of Arizona where he held the position of assistant irrigation engineer. Later he was transferred to the teaching college and held the positions of assistant and associate professor of civil engineering, until May, 1919. In June, 1919, he became head of the Civil Engineering Department of the University of Arizona as professor, a position he held at the time of his death.

He was joint author with O. E. Meinzer of a paper on the "Geology and Water Resources of Sulphur Spring Valley, Arizona," published as *Water-Supply Paper No. 320* of the U. S. Geological Survey.

On June 9, 1906, Professor Kelton was married to Eleanor H. Harrison, who, with their three sons, Kenneth Otis, Frank C., Jr., and Raymond Harrison, survives him.

The Society listed his nature of business as "instruction," and he loved it. His students are scattered all over the world. His interest in youth and its development was unwavering. He was faculty adviser for the University of Arizona Student Chapter of the Society from its organization (1926) until his death. The success of this chapter was due to his unstinted efforts and guidance, and poor health in the last few years failed to hamper his work with this group. He was president of the Arizona Section in 1932, which, in extending condolences to his wife, adopted the following resolution as an expression of the Section's feeling regarding him:

> "WHEREAS, a member of long standing has been lost to the Arizona Section of the American Society of Civil Engineers, and
>
> "WHEREAS, it is fitting and proper that his record should be reviewed and recorded,

---

[1] Memoir prepared by John H. Gardiner, M. Am. Soc. C. E.

"THEREFORE, be it resolved by the Arizona Section, assembled at Tucson, Arizona, this second day of May, 1942, that the following record be spread upon the minutes and that copies be sent to members of his family and to the Headquarters of the Society.

"Frank Caleb Kelton joined the American Society of Civil Engineers as an Associate Member in 1912 and was made a full Member in 1926. He was President of the Section in 1932. In 1926 he organized the University of Arizona Student Chapter and was its advisor until the time of his death.

"He was a faithful and valued member of the Society and of the Section. He considered Society affairs of first importance and discharged the duties imposed by it with meticulous care. The affairs of the Student Chapter were always uppermost in his mind and heart. He made the Student Chapter one of the best in the Country, and invested its meetings with importance and conducted them with dignity. He served always with energy, great attention to detail and complete thoroughness. His performance will be hard to duplicate.

"He was a man of great courage and strength, unswerved by winds favorable or adverse. He carried on without fear, completely uninfluenced by considerations which sought to turn him from the path he thought to be right. His example will be long remembered. The Society has suffered an irreplaceable loss."

Professor Kelton was a man of determined character and one who loved his home and his family. He felt keenly his obligation to his fellow men, and his career enlarged and enriched all his human relations.

He was a member of Phi Kappa Phi honorary fraternity, Kappa Sigma, and the Society for the Promotion of Engineering Education.

Professor Kelton was elected an Associate Member of the American Society of Civil Engineers on February 6, 1912, and a Member on October 1, 1926.

CHARLES HANFORD KENDALL, M. Am. Soc. C. E.[1]

DIED DECEMBER 10, 1941

Charles Hanford Kendall was born on May 27, 1872, in Rushford, Allegany County, N. Y., the son of Charles Bemus Kendall and Antoinette (Smith) Kendall. He attended the public schools of Rushford between 1886 and 1890. He entered Cornell University, at Ithaca, N. Y., in 1891 and was graduated in 1895 with the degree of Civil Engineer. In 1896 he received the degree of Master of Science from the University of Minnesota, in Minneapolis, which he attended from 1895 to 1897.

During 1897 and part of 1898, he was employed by the Central Railroad Company of New Jersey on valuation engineering work. In 1898 and 1899, he was employed as locating engineer on the Guayaquil and Quito Railroad in Ecuador, South America. This work was in the wild country of the Andes

---

[1] Memoir prepared by J. D. Fauntleroy and G. G. Wickline, Members, Am. Soc. C. E.

Mountains, and transportation for supplies and equipment was by pack mule. From 1899 to 1901, he was employed as maintenance engineer with the Pittsburg, Shawmut and Northern Railroad Company in Pennsylvania.

From 1901 to 1907 Mr. Kendall was with the U. S. War Department in the Philippine Islands—first, as provincial supervisor of public work of Batangas Province for two years; second, as railroad engineer for two years; and for four years he was assistant director of public works. He remained in this province about two years and then was promoted to assistant engineer to James W. Beardsley, M. Am. Soc. C. E., consulting engineer for the insular government, and was placed in charge of "Surveys for the Friar Lands." Much of this work was in the region of the fierce-fighting Moro natives. During this period he acquired a large collection of native bolo knives and spears. His work was mostly on the island of Luzon, but he also worked on other islands of the Philippine group, including Mindanao, where he was located in the City of Davao. He received much credit for the manner in which this work was completed.

He then received an offer from the Manila and Dagupan Railway Company to take charge of extensive surveys that the company was making, and thereupon left the government service. After several years of service with the railroad company, he returned to the United States because of the serious illness of his parents. While in the Philippines, he was married to Elizabeth Mullen in Manila in 1906.

During the period from 1909 to 1914, Mr. Kendall engaged in private engineering practice at Buffalo, N. Y., and Washington, D. C., in various capacities. In April, 1914, he was employed by the U. S. Public Roads, in which capacity he served until 1919. During this period he had the title of U. S. Senior Highway Engineer and served on location and construction of forestry roads and national parks, and also in connection with certain duties in the Washington Office pertaining to forestry roads. Some of his duties carried him into the states of Idaho and Utah. He worked under the supervision of T. Warren Allen, M. Am. Soc. C. E., formerly chief of the Division of Control of the U. S. Bureau of Public Roads and earlier chief of the Division of Forest and Park Roads.

Mr. Kendall's next assignment came in 1919; he was transferred to Fort Worth, Tex., and served for a period of eight months in District 6 of the Public Roads Administration. In 1919 he was employed by the State Highway Department of Texas as assistant state highway engineer, which position he held for three years. From July, 1922, to May, 1927, he was county engineer in Fort Bend County, Texas, and was stationed at Sugar Land, Tex., at which place he had supervision over an extensive highway improvement program on U. S. Highway 59, known at that time as State Highway No. 3. During this period of employment, Mr. Kendall had charge of work between the Harris County line and the City of Richmond, Tex. This work included grading, structures, paving, and the building of a large bridge across the Brazos River for which he supervised the engineering work. The highway designed by Mr. Kendall had a typical cross section with side slopes of 1 on 6, which many engineers at that time considered extremely flat and a considerable waste of money. The value of this added safety factor to the road was apparent after its completion. This served as a forerunner for the flat slopes for the highway shoulders in the State of Texas, which no doubt has been a factor in the saving of lives and in the reduction in the number of accidents. This practice has since been followed by quite a number of states in the United States. Mr. Kendall generally is regarded as being the originator of the plan for building flat slopes on the highways of Texas.

In May, 1927, Mr. Kendall's work was completed in Fort Bend County and he was employed as resident engineer for the State Highway Department in Brooks County, where he remained for a period of one year to supervise the engineering work of a concrete highway. This highway is the main route out of the Rio Grande Valley for the shipment of winter vegetables and fruits to northern points.

From 1928 to October, 1930, Mr. Kendall served as resident and county engineer in Anderson County, Texas, with headquarters at Palestine, where he had supervision of the building of considerable portions of new highways for the State Highway Department. In October, 1930, he became resident engineer for the State Highway Department in Tyler County, Texas, with headquarters at Woodville. He held this position until June, 1938. For a short period of time he served on special assignments with the Maintenance Division of the State Highway Department, with various miscellaneous projects over the State of Texas. In May, 1939, Mr. Kendall began residence at Pecos, Reeves County, Tex., where he served with the District Highway Engineering Office, first as field engineer on location, and later as a special office engineer.

In the performance of his duty on December 9, 1941, Mr. Kendall received injuries that resulted in his death. He was returning from an engineering assignment with another engineer when the car overturned because of a tire blowout. He is survived by one daughter, Elizabeth Kendall. His wife passed away in Pecos in 1941. His son, Horace Kendall, died on January 1, 1924, at the age of twelve, in Sugar Land.

Mr. Kendall was noted for his energy and friendly attitude toward all people. He had a great host of friends to whom he was very generous. He spent much of his time and effort in helping to provide comfort and pleasure for his friends and others. He possessed an unusually tender heart and a sympathetic understanding of his fellow men, and his passing is grieved by his many friends.

Because of the fact that he had seen engineering service in practically all parts of the United States, in South America, and in the Philippines, he had a great number of very interesting experiences. He had a collection of various art objects and souvenirs, instruments of warfare, and fishing equipment that he acquired in various sections of the world. He had thirteen large trunks of souvenirs and books packed away in a storage house in San Antonio, Tex. Mr. Kendall was a great lover of books, and he had a large library covering many subjects. He was also fond of hunting and fishing. One of his happiest periods of relaxation was in fishing. Had he lived until May 27, 1942, he would have been seventy years old. He had been notified of his change to the life membership grade in the Society as of January 1, 1942.

Mr. Kendall was elected a Member of the American Society of Civil Engineers on November 6, 1907.

WILSON SHERMAN KINNEAR, M. Am. Soc. C. E.[1]

DIED AUGUST 8, 1941

Wilson Sherman Kinnear was born at Circleville, Ohio, on May 25, 1864. He was the son of Richard and Mary Hall (Crew) Kinnear. During the years that he was in the public schools he often accompanied his father on survey parties and thus early acquired a liking for, and the ambition to become a member of, the engineering profession. He matriculated at the University of Kansas, at Lawrence, Kans., as a member of the class of 1884, and remained in college two years, leaving school at the end of his junior year to enter railway service. At the commencement of the class of 1907 he was granted the degree of Civil Engineer by the University.

In 1883 and 1884 he served as axman, rodman, draftsman, leveler, and transitman with the Atchison, Topeka and Santa Fe Railroad Company; from the autumn of 1884 to the autumn of 1885 he was assistant engineer of the Kansas City, Clinton and Springfield Railway Company; in 1885 and through the year 1886 he was division engineer for the Gulf, Colorado and Santa Fe Railway Company. With this background of early surveying experience prior to his college work, followed by three and a half years of experience in railway location and construction during the most active period of railway building the nation ever had, he went to Los Angeles, Calif., and during 1887 and 1888 was engaged in hydraulic engineering work. Late in 1888 he was employed by the North and South American Construction Company, of Santiago, Chile, first as office engineer, then assistant chief engineer, and after a few weeks as acting chief engineer in charge of the construction of railways, which constituted a very large part of the program of internal improvements which had been inaugurated by President José Manuel Balmaceda.

By the autumn of 1889 the opposition to President Balmaceda had become so powerful and the coming Revolution was so evident that Mr. Kinnear left Chile "while the going was still good" and returned to the United States. In February, 1890, he was employed by the Michigan Central Railroad Company as supervising engineer in charge of construction of second track on the Canada Southern Railroad between Buffalo, N. Y., and Windsor, Ont., Canada.

Mr. Kinnear served the Michigan Central Railroad Company for twenty years, during which time his advancement was rapid. He held the positions of assistant engineer on maintenance of way and construction; supervising engineer on the construction of the Toronto, Hamilton and Buffalo Railroad for the Michigan Central; principal assistant engineer; assistant superintendent; assistant general superintendent; chief engineer; and assistant general manager.

---

[1] Memoir prepared by Henry E. Riggs, Past-President and Hon. M. Am. Soc. C. E.

During the period 1904 to 1910 the Michigan Central was engaged in the design and construction of the Detroit River Tunnel. Previous to the completion of the tunnel all trains had been ferried across the river at Detroit, Mich., at great expense and with much inconvenience and delay.

In 1904 Mr. Kinnear was named a member of a committee of which William J. Wilgus, Hon. M. Am. Soc. C. E., then Vice-President of the New York Central and Hudson River Railroad, and the late E. A. Handy, M. Am. Soc. C. E., then chief engineer of the Lake Shore and Michigan Southern Railway Company, were the other members. This committee had the responsibility of reporting on the feasibility of building a tunnel beneath the Detroit River. Following its favorable report and the decision to proceed with the work, an advisory board was appointed composed of Mr. Wilgus as chairman, Mr. Kinnear, and the late Howard Adams Carson,[2] Hon. M. Am. Soc. C. E. Mr. Kinnear was appointed assistant general manager of the Michigan Central and chief engineer of the Detroit River Tunnel Company, and the late Benjamin Douglas,[3] M. Am. Soc. C. E., was appointed tunnel engineer.

The underwater conditions in the Detroit River, owing to the extreme depth of rock, the light covering over the tunnel, and the poor character of the clay through which the tunnel must be built, were such as to make the use of the usual shield-driven tunnel hazardous and highly undesirable. Four methods of construction were considered and the advisory board finally decided upon a method conceived and presented by Mr. Wilgus and supported by Messrs. Kinnear and Carson. This trench and tremie method was novel and untried, and was at the time severely criticized by prominent engineers; but it was adopted.

The job was completed under this engineering organization: The trench was dug across the bed of the river; the steel tunnel shell or core was built about thirty miles north of the tunnel site, floated to place, sunk, connected up and anchored; the concrete was placed using the tremie or bucket deposit method; and, finally, the shore sections and the river tunnel were connected—all without any serious difficulty or delay. Mr. Kinnear was chief engineer of the work from start to finish.

The record of the conception and completion of this remarkable achievement is filed in the Engineering Societies Library[4] among the professional papers of Colonel Wilgus and is splendidly summarized in the paper by Mr. Kinnear, "The Detroit River Tunnel."[5] This paper resulted in the award to Mr. Kinnear in 1912 of the Norman Medal.

In connection with the building of the tunnel Mr. Kinnear had charge of the design and construction of the electrified terminals of the Michigan Central Railroad in Detroit and Windsor, and of the construction of the electrified section of the main line through the tunnel connecting the two terminal yards.

---

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 96 (1932), p. 1386.
[3] For memoir, *ibid.*, Vol. LXXV, December, 1912, p. 1151.
[4] 29 West 39th St., New York, N. Y.
[5] *Transactions*, Am. Soc. C. E., Vol. LXXIV, December, 1911, pp. 288–374.

In 1910, upon completion of the tunnel, Mr. Kinnear was offered, and he accepted, the presidency of the Kansas City Terminal Railway Company, which had just begun the construction of the new Union Station. Under his supervision the plans were perfected for the complete reconstruction of the Belt Line railway, the Union Station, and all adjacent improvements; contracts were let; and the entire major project was nearing completion before he severed his connection with it. As one of the engineers who was on this work expressed it, "Mr. Kinnear and the men he brought with him from the Detroit River Tunnel were the whole thing."

On May 1, 1912, Mr. Kinnear resigned and went to New York, N. Y., as president of the United States Realty and Improvement Company, serving until January 1, 1918. He organized the U. S. Realty and Improvement Construction Company, which built many major projects in New York, among them being the Harlem River four-tube subaqueous tunnel of the Lexington Avenue Subway; the Hell Gate Bridge foundations, including all the foundations from Bronx Kills Bridge to the Long Island Viaduct piers at Stemler Street; Section Two of the Broadway Subway; and two sections of the Seventh Avenue Subway.

On January 1, 1918, he organized the firm of W. S. Kinnear and Company, Consulting Engineers, and continued in private practice until 1936 when he retired and moved to Detroit to make his home with his daughter. During these sixteen years his practice was of a broadly diversified nature and included many engagements on major work of great importance.

Mr. Kinnear was a member of Beta Theta Pi fraternity and of Sigma Xi honorary scientific fraternity. He was a member of the Detroit Club, the Detroit Golf Club, and the Union League Club of New York City, and the Sleepy Hollow Country Club, of Tarrytown, N. Y. He was a member of the American Railway Engineering Association, and a member and Past-President of the American Institute of Consulting Engineers.

Mr. Kinnear was married in 1887 to Carrie M. Nichols of Springfield, Ohio, who died in September, 1932. Surviving are a daughter, Carmen (Mrs. Elwood Johnson), and a son, Lawrence Wilson Kinnear.

Wilson Sherman Kinnear was an able engineer and an excellent executive. The magnitude of the work that he did and its diverse nature easily entitles him to rating as one of the Master Builders of his generation. He was a man of fine personality who made a host of friends both in his profession and in the social circles in which he moved.

Mr. J. C. Mock, retired Signal-Electrical Engineer of the Michigan Central, who was intimately associated with Mr. Kinnear on the Michigan Central System and the Tunnel, gives the following estimate of his personality:

> "His six feet four inches in height, carried with modest dignity, distinguished him in any company. His humanity and kind consideration for those associated with him professionally made them his friends, insured him unquestioned loyalty, and largely accounts for his excellent record as an organizer and coordinator."

Mr. Kinnear was elected a Member of the American Society of Civil Engineers on July 9, 1906.

STUART KELSEY KNOX, M. Am. Soc. C. E.[1]

Died June 28, 1941

Stuart Kelsey Knox, the son of Judge David M. and Maria Louise (Kelsey) Knox, was born in Three Rivers, Mich., on May 8, 1879. He attended the University of Michigan at Ann Arbor, Mich., and was graduated with the degree of Bachelor of Science in Civil Engineering in 1903. While obtaining his technical education he gained practical experience with the Oldsmobile Company of Detroit, Mich.; the city engineer of Sault Ste. Marie, Mich.; International Transit Company, Sault Ste. Marie, Ontario, Canada; and the late Clarence G. Wrentmore, M. Am. Soc. C. E., consulting engineer of Ann Arbor.

Mr. Knox's first engagements after graduation were with the United States Engineers' office on pier and revetment construction at Muskegon, Mich., and with consulting engineers on irrigation surveys in Texas. From July, 1904, to August, 1907, he was employed by the Thompson-Starrett Company, Inc., of New York, N. Y., on construction of such buildings as the Continental Trust Building in Baltimore, Md.; the Kenesaw Apartment Hotel and Union Station in Washington, D. C.; and the United States Express Building in New York City. He was superintendent of construction for the Foundation Company of New York City on work in Washington, D. C., from September, 1907, to December, 1907.

In January, 1908, Mr. Knox joined the staff of the late Nicholas S. Hill, Jr.,[2] M. Am. Soc. C. E., specializing in sanitary engineering work. He served as principal staff member until 1916, and then as an associate member of the firm until 1926, when he was admitted to a partnership that terminated in June, 1934. In this consulting engineering work he was identified with notable enterprises in the United States, Canada, Mexico, and Cuba.

During World War I Mr. Knox was chief designing engineer for all utilities at Camp Merritt, New Jersey, and engineer in charge of design and construction for the United States Housing Bureau in connection with its developments near Norfolk and Portsmouth, Va.

In January, 1935, Mr. Knox established a professional business as hydraulic and sanitary engineer that endured to the day of his death. Chief among the undertakings were water works rehabilitations at Binghamton, N. Y., and Montclair, N. J.

Mr. Knox's technical and professional affiliations included the American Society of Mechanical Engineers, American Public Health Association, American Water Works Association, and New York State Sewage Works Association. He was a contributor to the technical press.

Possessed of a keen, analytical, versatile mind, Mr. Knox was a man of great force of character and the utmost honesty, was exceptionally conscientious in his work, and was respected by his associates and his friends for his ability, integrity, and fundamentally sound principles of conduct.

---

[1] Memoir prepared by Samuel F. Newkirk, Jr., M. Am. Soc. C. E.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 103 (1938), p. 1808.

On June 8, 1914, he was married to E. Isabel Lane of Brooklyn, N. Y., at Wrentham, Mass. He is survived by a son, Stuart Kelsey Knox, Jr., and a brother, Edward M. Knox.

Mr. Knox was elected a Member of the American Society of Civil Engineers on April 2, 1913.

EDWIN WEED KRAMER, M. Am. Soc. C. E.[1]

DIED OCTOBER 31, 1941

Edwin Weed Kramer, the son of William Paul Kramer and Jean (Mobley) Kramer, was born at Louisville, Ky., on March 4, 1877. He obtained his technical education at Cornell University, in Ithaca, N. Y., and was graduated in 1905 with the degree of Civil Engineer.

Following his graduation from Cornell University, Mr. Kramer worked on the construction of the New York State Barge Canal, on dry docks for the U. S. War Department, and on other projects. Early in his career he chose the government service and served in that service continuously until his death. He entered the employment of the U. S. Forest Service in September, 1907, as construction engineer, at first employed in the Denver, Colo., office and later in Missoula, Mont., where he was designated district engineer, effective January 1, 1910. This district embraced Montana, northern Idaho, eastern Washington, and included in addition the National Forests in Minnesota, Wisconsin, and northern Michigan. The National Forests of the region in those early days consisted literally of primeval wilderness areas, practically without roads or means of communication. Transportation was effected generally by means of crude pack trails, and Mr. Kramer's initial work concerned the design and construction of bridges and other structures of the Forest Service improvement program. In 1913 he was promoted to hydraulic engineer and his activities broadened to include the field of water power administration. This embraced the issuance of permits covering hydroelectric developments utilizing land in the National Forests. In connection with this activity Mr. Kramer conducted notable investigations of the utilization of the Missouri River for power and other purposes.

The law creating the Federal Power Commission was passed in 1920 for the purpose of encouraging the development of water power resources under federal control. This law, combined with the spectacular increase of demand for electrical energy in California, resulted in an extensive program of hydroelectric development in that state. Since most of the power sites were in the National Forests, the administrative activities relating to the issuance and supervision of licenses were greatly increased. Mr. Kramer was called from Montana to serve as special assistant to the district engineer of the California District of the Forest Service, who was also serving as representative of the Federal Power Commission for the state. Throughout the decade of the

---

[1] Memoir prepared by Frank E. Bonner, M. Am. Soc. C. E.

1920's, when most of the great hydroelectric projects of California were being constructed, Mr. Kramer occupied a prominent position in the government administration phase of the program. During this period his technical work relating to the design of concrete arch dams was particularly noteworthy.

Mr. Kramer was advanced to the position of district engineer of the California District on July 1, 1929, and, in addition to directing all the Forest Service engineering activities of the state, he served as representative of the Federal Power Commission. The latter agency established a regional headquarters office at San Francisco, Calif., on July 1, 1936, to supervise the field activities of the seven western states, and Mr. Kramer was chosen to serve as regional director. He held this position until his death in 1941.

In connection with water power development, Mr. Kramer was always a staunch defender of the public interest, and in the course of his official duties he constantly endeavored to enforce the fullest scope of federal authority. His many years in the government service gave him a broad knowledge of the power and irrigation developments throughout the West, and as a result he was called upon frequently to serve as expert witness in litigation involving water rights and water uses.

Mr. Kramer was co-author of the reports published by the Federal Power Commission on "Uses of the Stanislaus River"[2] and "Uses of the American River."[2] He was author of "Construction of Fish Dams for Water Storage in California,"[3] and many articles in the technical press. He was also the author of "Curves for Determining Stresses in Arch Dams by the Cain Formula," which, although never published in their entirety, gained wide use among engineers designing arch dams. He was a member of the Sons of the American Revolution, and was a Spanish-American war veteran.

On June 22, 1905, he was married to Ruth Edwards. He is survived by his widow; by two sons, Edwin Weed Kramer, Jr., Assoc. M. Am. Soc. C. E., and Paul Kramer; by three daughters, Ruth (Mrs. Joel M. Popper), Jean Mobley (Mrs. Samuel H. Berry), and Margaret (Mrs. David Mealiffe); and by seven grandchildren.

Mr. Kramer was elected a Member of the American Society of Civil Engineers on December 14, 1925.

DWIGHT ARNOLD LANE, M. Am. Soc. C. E.[1]

DIED JULY 1, 1941

Dwight Arnold Lane was born at Boise, Idaho, on August 24, 1896, the son of Frank and Frankie (Arnold) Lane. He received his early education at Gardena, Calif., and later attended the University of Southern California, at Los Angeles, Calif.

---

[2] Federal Power Commission, 1927.

[3] U. S. Forest Service, 1935.

[1] Memoir prepared by Milton Anderson, Assoc. M. Am. Soc. C. E.

He entered the service of the Department of Water and Power, Bureau of Water Works and Supply, of the City of Los Angeles, in November, 1916, as chainman. He continued as such until he enlisted in the 26th Engineers, United States Army, on November 9, 1917. He served with this organization, as a part of the American Expeditionary Forces in France, in charge of a field party at Mesves, Bulcy Base Hospital, on water and sewer lines, buildings, railway lines, property surveys, etc. He also worked on the installation of a water system during the Meuse-Argonne drive and was with the Army of Occupation in Germany.

Upon his return to the United States and his discharge from the Army, Mr. Lane reentered the service of the Department of Water and Power, Bureau of Water Works and Supply, of Los Angeles, in April, 1919, as transitman in topographic surveys and water works construction. Later, he received appointments as draftsman, junior civil engineer, and finally assistant civil engineer.

It was during the time he was junior civil engineer that Mr. Lane rendered his important work of ground-water reconnaissance surveys and reports for the location and development of ground-water supplies for the City of Los Angeles. His supervision and general charge of irrigation studies and estimates of water demand, together with hydrographic and hydrologic information, formed the basis for the design, construction, and operation of water-spreading works. The recapture of water so spread, by his previously located water wells, was recognized as a water-conservation measure. It was also during this time that he became recognized as an authority on water rights. Under his direction were prepared engineering data and exhibits used in litigation in which he served as an expert witness.

His promotion to assistant civil engineer placed him in charge of Hydrologic and Engineering Investigations for the Los Angeles area, which included engineering research and collaboration with consulting engineers and governmental agencies, both state and federal, where his specialized knowledge was used to its best advantage. He continued in this capacity until his death.

On February 7, 1920, he was married to Gladys Show. He is survived by his widow; two sons, Dwight Arnold, Jr., and Kay Armand; and his father.

Mr. Lane was a member of Unity Lodge No. 368, Free and Accepted Masons, in Glendale, Calif.; Southern California Horticulture Institute; American Water Works Association; American Geophysical Union; and Aqueduct Post No. 342, American Legion, Department of California, of which he was a Past-Commander. For two years he was secretary of the Los Angeles Section of the Society.

Among his published papers were "Transforming Surface Water into Underground Storage,"[2] "The Loss of Wells in Construction and Operation,"[3] "Increasing Storage by Water Spreading,"[4] and "Artificial Storing of Groundwater by Spreading."[5]

[2] *Water Works Enginering*, September 2, 1936.

[3] *Journal*, A. W. W. A., October, 1932.

[4] *Ibid.*, April, 1934.

[5] *Ibid.*, September, 1936.

He had been in failing health for several years prior to his death; however, he was able to attend to his work until late in June, 1941, and died rather suddenly on July 1, 1941.

Dwight Arnold Lane was a quiet, unassuming gentleman. He was kind and sympathetic, interested in people whose pathways were beset with troubles and difficulties, always public-spirited, and ever ready to lend his aid and coöperate to the full in undertakings in which he could be of assistance. His passing marks the end of a life of service. He is missed and mourned by his host of friends.

Mr. Lane was elected an Associate Member of the American Society of Civil Engineers on December 15, 1924, and a Member on December 9, 1935.

SAMUEL HILL LEA, M. Am. Soc. C. E.[1]

Died March 28, 1941

Samuel Hill Lea was born at Marion, Perry County, Ala., on October 22, 1861, the son of Sumter and Susan I. (Hill) Lea. His maternal grandfather was a Colonel in the Mexican War, and his father served as Colonel in the Confederate Army.

Mr. Lea received his elementary school education in the public schools of his native city. At the age of twenty he was graduated from the Virginia Military Institute at Lexington, Va.

Soon after graduation, Mr. Lea entered the railroad engineering field in the South and served in various positions from levelman to locating engineer and resident engineer with several railroads. The latter included the Birmingham and Tennessee, the Sheffield and Birmingham, the Kansas City, Memphis and Birmingham, and the Louisville, St. Louis and Texas railroad companies.

During his early experience, Mr. Lea also engaged in a general engineering practice at Salem, Ala., in 1885 and 1886, at Fort Payne, Ala., from 1889 to 1891, and at Birmingham, Ala., from 1901 to 1904.

After several years of a wide and diversified experience on levee construction and maintenance, and on sewer projects and canal operation, he took charge of the construction of buildings, sewer system, and water supply at Fort Meade, S. Dak.

Mr. Lea's outstanding services at Fort Meade for the U. S. War Department brought him to the attention of the Governor of South Dakota who was seeking a suitable engineer to appoint to the newly created position of state engineer. In March, 1906, Mr. Lea became state engineer, a responsible public post which he filled with distinction for a term of seven years. He did pioneer work in the preparation of a State Irrigation Code; in the supervision of appropriations of water from non-navigable streams for irrigation, water power, and other beneficial uses; and in the direction of the construction of small dams across "dry draws" and valleys to conserve storm water and to prevent soil erosion. At the direction of the Governor, Mr. Lea supervised the building of the new State Capitol at Pierre. He planned the Capitol Park and lake and was responsible for the installation of a modern heating and air-conditioning system. The Hon. Harry L. Gandy, former congressman from South Dakota, wrote: "The South Dakota Capitol will stand as a monument to Mr. Lea long after he is dead."

---

[1] Memoir prepared by A. B. McDaniel, M. Am. Soc. C. E.

Returning to his native Southland in 1913, he served as city engineer of Charlotte, N. C., for four years. During this period he extended the paved streets into new sections and initiated important municipal improvements.

The highway field claimed Mr. Lea's professional talents in the later years of his life. He designed, laid out, and supervised the construction of highways in Mineral and Berkeley counties, West Virginia, from 1919 to 1923. During the following decade he was designing and estimating engineer with the Pennsylvania Department of Highways at Harrisburg.

In November, 1933, he was appointed engineer examiner for the Public Works Administration at Washington, D. C. On March 1, 1935, Mr. Lea left the federal service and retired to his home in Harrisburg. He passed out of this life on March 28, 1941, after an illness of several months.

Mr. Lea was married in New York, N. Y., to Bella B. Hackett of Easton, Pa., in 1901. After her death, he was married to Amy S. Le Van on November 26, 1930. He is survived by his widow.

A Mason, a devoted attendant of the Episcopal Church, and a faithful civic worker, Mr. Lea lived a life filled with interest in, and service to, his fellow men. Generous, kindly, and genial, he was well liked by his fellow workers. A man of high ideals, honesty, and integrity, he was impatient of careless and dishonest work and frank in his criticism of bureaucratic methods and political chicanery. As a facile writer, he wrote a treatise on "Hydrographic Surveying," issued a report on "Irrigation in South Dakota" while State Engineer, and contributed many articles to technical journals.

Mr. Lea was elected a Member of the American Society of Civil Engineers on November 3, 1897.

FRED HERBERT MARSH, M. Am. Soc. C. E.[1]

Died June 24, 1941

Fred Herbert Marsh was born on October 4, 1880, at Humboldt, Iowa, the son of Herbert W. and Ella J. (Harvey) Marsh. He received his early education in the public schools and was graduated from Iowa State College, at Ames, in 1904 with the degree of Bachelor of Science in Civil Engineering.

From 1904 to 1910 he was employed by various steel companies in Iowa and Colorado as draftsman and estimator, and on construction of all types of railroad structures and coal-mining equipment.

---

[1] Memoir prepared by A. B. Reeves, M. Am. Soc. C. E.

In June, 1910, he entered the employ of the Des Moines (Iowa) Bridge and Iron Works, which two years later became the Pittsburgh-Des Moines Steel Company. Here he was advanced through various positions to sales manager of the Des Moines office. In 1923 he resigned the latter position to become associated with the Paxton and Vierling Iron Works at Omaha, Nebr., as sales manager and member of the Board of Directors. In 1931 the management of this firm changed hands and Mr. Marsh retired from active connection with the company.

The next year was spent as estimator and designer for the Patterson Steel Company at Tulsa, Okla. Another year was spent on various jobs in connection with structural steel work.

In 1933 Mr. Marsh entered the employ of the U. S. Government with the War Department at Fort Lewis, Wash., on construction of improvements. Later he was transferred to the Bonneville Dam where, for more than three years, he was in charge of structural steel construction and inspection on the installation of the navigation lock gates.

Upon completion of the Bonneville job, he was transferred to the Pittsburgh, Pa., office, where he was employed on structural steel design. In July, 1938, he was transferred to the Denver, Colo., office of the Bureau of Reclamation, where he was engaged on structural steel design until his death.

Fred Marsh was a man who was helpful, cooperative, and considerate in his relations with others, and he had the good will and respect of all who knew him. Although he took very little part in political or social life, he was, for many years, active in local engineering groups and commercial organizations. He enjoyed hunting and fishing, and was interested in all outdoor activities.

On September 3, 1921, he was married to Eloise Winhafer. He is survived by his widow; three sons, Richard A., Edward H., and Frederick E.; and by his aged mother.

Mr. Marsh was elected a Member of the American Society on March 12, 1923.

CHARLES MEADS, M. Am. Soc. C. E.[1]

Died April 24, 1942

Charles Meads was born in Portsmouth, Va., on January 11, 1870, the son of Charles Meads and Anna (Herbert) Meads. He attended the schools of Portsmouth and Washington, D. C., and then entered the Corcoran Scientific School of the old Columbian University, at Washington, D. C., where he studied for two years.

Upon leaving school, he was employed as an architectural and structural draftsman. In 1894 he entered the employ of Richardson and Burgess, General Contractors of Washington, as an assistant superintendent of construction on contracts for power houses, car barns, and other structures for the Eckington Street Railway and the Columbia Railroad Company.

---

[1] Memoir prepared by Hugh J. Donnelly, Charles Meads & Co., New York, N. Y.

In 1896 Mr. Meads left Richardson and Burgess to work for R. H. Hood, M. Am. Soc. C. E., as an estimator and superintendent of construction on various public works contracts, including buildings in the Washington Navy Yard, car sheds for the Washington and Alexandria Railroad Company near Alexandria, Va., and car sheds for the Metropolitan Railroad Company of Washington. In 1897 Mr. Hood moved his main office to New York, N. Y., and Mr. Meads remained in Washington in charge of the Washington office. In 1898, upon the closing of the Washington office, Mr. Meads moved to New York, where the R. H. Hood Company had been incorporated. As an officer in this company, he was associated for several years with Mr. Hood and the late Daniel A. Garber, who subsequently formed the North Eastern Construction Company and who was also the organizer and first president of the General Contractors Association in New York. The R. H. Hood Company engaged in the construction of many large municipal and government projects in New York City from 1898 to 1904, including the Main Immigration and Hospital Buildings on Ellis Island in New York Harbor, the steel floor and concrete foot-walk construction of the Williamsburg Suspension Bridge, and the construction of four lift bridges over the Gowanus Canal in Brooklyn, N. Y.

Mr. Meads organized and became president of Charles Meads and Company in 1904, and of the Meads Engineering Company, Inc., in 1931. These companies have been engaged in engineering and contracting work in New York City continuously since their organization. Under his direction as President, they have completed a long list of municipal and government projects. Among these are the Lighthouse of Lloyd Harbor, Long Island, N. Y.; the first contract for the Central Building of the Brooklyn Public Library; the Municipal Ferry Terminal at the foot of 39th Street, Brooklyn; the steel viaduct and upper level approaches of the Bronx Terminal Market; the reconstruction of the old Elevated Station on the Interboro Rapid Transit (I.R.T.) at the World's Fair Grounds in Flushing, changing this from a small local station to a large express station, and the extension of the Independent Subway into the World's Fair Grounds, including the Terminal Station. Perhaps the most notable work done by his companies was the construction between 1928 and 1940 of more than eighty subway stations of the Independent Subway System in New York City, as well as many elevated railroad stations, and the very difficult work of lengthening existing subway stations.

During World War I, Mr. Meads' company was engaged almost exclusively on projects for the U. S. Navy, including several large warehouses in the Brooklyn Navy Yard, service buildings and utilities at the Rockaway Beach Naval Air Station, the Naval Air Stations at Chatham, Mass., and Hampton Roads, Va., and the construction of the U. S. Marines Flying Field at Quantico, Va.

Mr. Meads was active in the affairs of these companies up to the time of his death. He brought to the field of public works contracting a high sense of honor and obligation to the public good. He always believed that a successful business in public works contracting could be run with only the highest standards of business and professional ethics. He followed these beliefs consistently with success throughout his entire business career of fifty years.

Mr. Meads was a member of the Brooklyn Engineers' Club, an associate of the Municipal Engineers of New York City, and a member of the American Military Engineers.

He was married in Washington, D. C., on October 24, 1894, to Jean Estelle Reeves, who, with one daughter, Estelle (Mrs. Charles Crane) survives him. His home was in Mountain Lakes, N. J.

Mr. Meads was elected a Member of the American Society of Civil Engineers on September 6, 1910.

THADDEUS MERRIMAN, M. Am. Soc. C. E.[1]

Died September 26, 1939

Thaddeus Merriman, eminent civil engineer and life-long student of science, died prematurely in the full tide of his mental activity and richness of engineering experience. He left, only partly finished, extremely valuable original researches in the nature and manufacture of Portland cement, but the results of his studies were and are already in wide use.

Mr. Merriman was born in New Haven, Conn., on April 6, 1876. His father was Prof. Mansfield Merriman, well known to all civil engineers by his treatises on hydraulics and other engineering subjects and his *Civil Engineers' Handbook*. He was especially well known to the many students who had the benefit of his personal teaching at Lehigh University, Bethlehem, Pa. Professor Merriman was of New England stock, his ancestor, Capt. Nathaniel Merriman, having come to America in 1632. Thaddeus Merriman's mother was Wanda (Kubale) Merriman. She was born in Germany where Professor Merriman met her after his graduation from Yale University, at New Haven. She was a warm-hearted, sensitive, generous woman, and her son Thaddeus much resembled her in these and other ways.

On January 12, 1904, Thaddeus Merriman was married to Margaret Mather, a Vassar graduate, of New Haven, Conn. It happened that her father and Mr. Merriman's father were classmates at Yale. She and their two children survive him. Their only son, Mansfield, is associate geologist for the U. S. Bureau of Reclamation. The only daughter, Margaret Mather Merriman, Ph.D., is married to W. George Parks, who is (1941) Professor of Chemistry at Rhode Island State College, at Kingston, R. I. The scientific bent remains strong in the family.

Thaddeus Merriman was graduated from Lehigh University in 1897 with the degree of Civil Engineer, receiving the degree of Doctor of Engineering in 1930. He began his engineering experience even before entering college by summer work as rodman, in 1891, at the age of fifteen. Two years later he spent another summer as draftsman at the Bethlehem Iron Company, South Bethlehem, Pa. The following three summers were likewise spent in getting practical engineering experience, each year in a different way.

---

[1] Memoir prepared by Thomas H. Wiggin, M. Am. Soc. C. E., and Mansfield Merriman, Bureau of Reclamation, Denver, Colo.

The year and a half following graduation were spent in a geological survey of western Pennsylvania and then on water works construction in New Britain, Conn. From December, 1897, to July, 1900, Mr. Merriman was engaged in increasingly important positions as rodman, transitman, draftsman, and computer, and finally assistant engineer and chief of party on studies and surveys for a canal across Nicaragua, Central America, to connect the Atlantic and Pacific oceans. The early part of this work was in Washington, D. C., but the last year was spent in the field in Nicaragua with the U. S. Isthmian Canal Commission. This experience in the wilds was greatly to his taste and, to those who knew him in later life, its influence was apparent in the acuteness of his engineering field sense and his appreciation of the romance of pioneer engineering.

In the fall of 1900 and the spring of 1901, Mr. Merriman was designer with the New York Continental Jewell Filtration Company, a newly formed amalgamation of three active filter companies which had received the contract for equipping the first of the modern, masonry, rapid sand filter plants. This pioneer plant of 32 mgd capacity, designed by the late George W. Fuller[2] and William B. Fuller,[3] Members, Am. Soc. C. E., and based on the historic filter experiments of George W. Fuller at Louisville, Ky., attracted Mr. Merriman, who participated during the period of its development.

From March, 1901, to April, 1902, Mr. Merriman returned for a time to the steel business as inspector, in the United States, of bridge and other material used in the construction of the Guayaquil and Quito Railroad Company of London, England.

In April, 1902, Mr. Merriman began his long career in water supply design and construction, serving for two years as assistant engineer and one year as division engineer in charge on the construction of the important masonry dam at Boonton, N. J., built by the Jersey City Water Supply Company. During this latter period Mr. Merriman also did work for the group of water companies affiliated with the East Jersey Water Company and the parent Society of Useful Manufactures, a society founded by Alexander Hamilton. This group of companies has been served by such other celebrated hydraulic engineers as the late Clemens Herschel,[4] Past-President and Hon. M. Am. Soc. C. E., inventor of the venturi meter (which should have borne his name), the late J. Waldo Smith,[5] Hon. M. Am. Soc. C. E., one time chief engineer of the Board of Water Supply under whom the Catskill water system was built and who preceded Mr. Merriman in that position, and the late Allan W. Cuddeback,[6] M. Am. Soc. C. E.

[4] For memoir, *ibid.*, Vol. 95 (1931), p. 1419.

[5] For memoir, *ibid.*, Vol. 101 (1936), p. 1502.

[6] For memoir, *ibid.*, Vol. 105 (1940), p. 1815.

The Boonton dam is believed to be the first Cyclopean masonry dam. This masonry, invented or at least first used in dams by William B. Fuller, Mr. Merriman's chief on the Jersey City water supply work, consisted of large stones up to about 2 cu yd in volume embedded in concrete instead of being set in mortar. The exterior faces of the Boonton dam were of squared stone masonry. Since the large dams subsequently built for the New York water supplies were also of Cyclopean masonry, this first experience of Mr. Merriman in the construction of a large dam is of note.

In this dam also were placed electric thermometers, perhaps for the first time in such a dam, and the observations of the high setting temperatures of masses of Portland cement concrete colored Mr. Merriman's subsequent work on large dams and on the technique of cement manufacture and use.

In August, 1905, Mr. Merriman was one of the nucleus of engineers assembled by J. Waldo Smith for his first report as chief engineer of the Board of Water Supply on the Catskill water system for the City of New York. This first report had the benefit of the 1903 report of the Burr, Hering, Freeman Commission on "Additional Water Supply for the City of New York," but it was made with incredible celerity—namely, in August and September of 1905. Mr. Merriman had an important part in it; his estimates of dam and aqueduct cost, made quickly and with apparent roughness, yet with a nice regard for the precision warranted by the available data, furnished much of the basis of the estimates of cost of about $162,000,000 for this great undertaking. These estimates subsequently were found close to the actual cost of the work.

Following the acceptance of the Catskill plan and the beginning of its construction, Mr. Merriman went to the Reservoir Department of the Board of Water Supply engaged in the construction of the huge Ashokan (N. Y.) Reservoir of 120 billion gallons capacity. His work in that department between November, 1905, and April, 1907, was as assistant engineer and then division engineer on surveys and studies for the main dam and the dikes.

In 1907 Mr. Merriman became assistant to J. Waldo Smith at the main office in New York, N. Y., his title being, at first, division engineer and then department engineer. This work continued through the most active period of design and construction of the Catskill water supply system. Between August, 1914, and February, 1918, he was department engineer in charge of Headquarters Department. This section was charged with preparation of designs, specifications and reports, the inspection of material, and keeping records, personnel, etc. The most active work during this period was the completion and testing of the Catskill aqueduct and City tunnel and the design of the Gilboa dam and Shandaken tunnel for impounding the waters of Schoharie Creek, bringing them through the mountains to Esopus Creek, whence they flow into Ashokan reservoir and become available for supplying the city through the Catskill aqueduct.

From February, 1918, to June, 1922, Mr. Merriman was deputy chief engineer of the Board of Water Supply of the City of New York, and in June, 1927, he succeeded J. Waldo Smith as chief engineer. He retired on November 29, 1933, but continued an active interest in the work while engaged in private practice. In September, 1936, he was appointed consulting engineer to the Board, a position which he held until his death.

Mr. Merriman's work as deputy chief engineer and chief engineer of the Board of Water Supply saw the completion of the Schoharie dam and Shandaken tunnel, also the surveys, geological investigations, and the preparation of preliminary plans for the additional supply of water to New York City from the Rondout watershed, the Neversink, and the East Branch of the Delaware. The original plans contemplated an additional supply of 760 million gallons but, except for the 100 mgd from Rondout Creek, the water to be taken was interstate water flowing into the Delaware River and affecting the interests of the states of New Jersey and Pennsylvania. These states took their case to the courts and an important legal battle resulted which was finally settled in 1931 by the U. S. Supreme Court. This decision awarded the City of New York 440 mgd of the 660 mgd asked for from Delaware River sources, but gave the city the right to apply for more when it was needed.

In this case, Mr. Merriman took a leading part both as witness and as collaborator with the Corporation Counsel of the City of New York, Arthur J. W. Hilly. Mr. Merriman wrote the engineering and much of the legal parts of the brief and was credited, not only by his own board but by Corporation Counsel Hilly, as the major contributor to the successful outcome.

Among the interesting interludes during his employment on the water supply of New York City was a period of about five months in the fall and winter of 1919–1920, on leave from the city. This time was spent in company with a former colleague, William E. Swift, M. Am. Soc. C. E., on behalf of the firm of Ford, Bacon and Davis, Engineers, making a field investigation and report on a ground-water supply for the City of Athens, Greece.

During at least twenty-five years of his employment with the Board of Water Supply of New York City, Mr. Merriman pursued original studies into the nature, behavior, and manufacture of Portland cement. The laboratory of the Board of Water Supply had begun these studies as early as 1907, but in the later years the studies were in great part guided by Mr. Merriman. He was stimulated in these studies by the experience in the New York water supply and elsewhere as to the destruction by solution, frost, and weather of concrete structures. His studies led to new specifications for the manufacture of sulfate resistant Portland cement, which were adopted in 1933 for the Fort Peck Dam in Montana. His further studies resulted in the specification adopted by the Board of Water Supply of the City of New York for the Delaware water supply project, and soon thereafter on other important hydraulic works. The Metropolitan District Water Supply Commission of Massachusetts used this cement in its great reinforced concrete pipe, the Department of Power and Water of the City of Los Angeles now (1941) uses it in the lining of its steel pipe, and private concerns have used it for pipe linings.

Mr. Merriman's specifications provide for both laboratory and manufacturing control. Experiment and experience demonstrated to him the necessity for control of the burning zone temperature, as indicated by recording pyrometers, the time of burning, as determined by the rate of kiln rotation, the protection of the clinker from exposure to the weather or other access of moisture and a limitation on the age of the clinker before grinding. They also provided for the limitation of alkalinity and water soluble alkalis, for the fixing of a minimum percentage of silica, of a maximum lime-silica ratio, of a maximum molecular ratio of lime to the sum of silica, alumina, and ferric-oxide (Colony's ratio), of maximum percentages of alumina and a maximum alumina-iron ratio. A sugar solubility test was also devised as a laboratory check to indicate the thoroughness of burning. This, together with other manufacturing and chemical controls, he believed essential to the production of a consistently high-grade cement that could be depended upon to make durable concrete. The sugar solubility test has been included in the 1938 and later cement specifications drawn by the Metropolitan Water District of Southern California and has been used by private companies in purchasing low solubility cement for water pipe linings.

Those who have critically used cement, made in accordance with these specifications, have generally remarked on the greatly diminished production of laitance, the diminished tendency to cracking, and the greater resistance to destruction by saturation and frost action. It is too soon for a final appraisal of Mr. Merriman's work on cement, but there is no room for doubt as to the value of his analysis of the imperfections of cement, his emphasis on the importance of finding remedies, and his insistance on care of the clinker in manufacture. He infused life into a too dormant field of chemical and engineering inquiry and it is regrettable that he could not have lived to carry his researches further and lend his great influence to keeping this important study alive until it was further along toward final and unquestioned solution.

During the period from his retirement in 1933 from the chief engineership of the Board of Water Supply of the City of New York until his death, Mr. Merriman was called to act as consulting engineer on a number of large hydraulic projects. He was chairman of the Board of Review of the Metropolitan Water District of Southern California in its project for supplying water from the Colorado River. He was also consultant on the Fort Peck project in Montana, on flood control projects in Los Angeles and Orange counties in California, and consultant to the Tennessee Valley Authority on Norris and other large dams, to the Water Power and Resources Board of the Commonwealth of Pennsylvania and to the Metropolitan District Water Supply Commission of the Commonwealth of Massachusetts.

To his father's and his own school, Lehigh University, he contributed of his knowledge and experience by lecturing on hydraulics and water supply. Mr. Merriman was a life-long student of pure science apart from his study of applied science in engineering. In 1933 he submitted to the American Association for the Advancement of Science a mathematical paper entitled "Gravitation in Terms of a Substantive Æther." Few of his friends know of the sustained interest and thought given to the theories concerning gravity, inertia, mass, and energy. He left a partially completed book entitled

"Reality," on which he had been working for more than thirty years, and dedicated, "To my wife, whose help and patience through many years finally made it possible for me to visualize a little of the reality of the universe in which we live." The material is being assembled and compiled for publication by his son. Another complete paper on "A Kinetic Theory of Hydraulic Flow" was likewise never published.

Apart from his necessary engineering reports and briefs, Mr. Merriman was not a prolific writer. His brief on the Delaware project for the U. S. Supreme Court has been mentioned, also his monographs on Gravitation, on Reality, and on Hydraulic Flow. In recent years he wrote much on Portland cement, mostly in the organization paper of the Board of Water Supply called "Delaware Water Supply News." His views on Portland cement are also given in a paper presented before the Boston Society of Civil Engineers on October 19, 1938.[7] The intense activity of his professional life together with his insistence on "understanding" was responsible for the small number of his published articles. One of his favorite sayings was to the effect that finding an obscure detail and assigning it a name did not constitute a discovery.

He enjoyed nothing more than to be with his family. His relaxation was invariably found out of doors as a woodsman, fisherman, canoeist, and archer. He was no stranger to the mountains and streams from Maine to California, yet the near-by woods held equal attraction. In the field he was always the geologist and student of land forms, instilling his interest in all about him. He often sought and found evidences of much greater floods than any experienced within recent times, and believed in making spillways for dams as large as the physical conditions would permit. Later, his activity in engineering left him too little time to follow the leisure that gave him so much contentment.

Endowed with a most sociable personality, he enjoyed the companionship of a few or large group of friends and associates. He knew the popular songs and was fond of leading a group in a serious rendering of "Nellie Gray."

He lived a many sided life, bringing to each subject the illumination of a scientifically trained, keen, logical, and resourceful mind and, withal, giving a surprisingly large amount of time to the obligations of friendship.

Mr. Merriman belonged to the following societies, appropriate to his many interests: American Association for the Advancement of Science, The Franklin Institute, American Society for Testing Materials, American Concrete Institute, New England Water Works Association (Honorary Member), American Water Works Association, Merchants Association of New York, Century Association of New York, Arkwright Club, Engineers Club, Engineering Foundation (Chairman of Research Committee), and Tau Beta Pi and Sigma Xi fraternities.

Mr. Merriman was elected a Junior of the American Society of Civil Engineers on April 4, 1899, an Associate Member on April 1, 1908, and a Member on December 6, 1910.

---

[7] "Portland Cement," by Thaddeus Merriman, *Journal*, Boston Soc. of Civ. Engrs., Vol. XXVI, January, 1939, p. 1.

CHARLES HAMILTON MITCHELL, M. Am. Soc. C. E.[1]

DIED AUGUST 26, 1941

After twenty-two years of service as Dean of the Faculty of Applied Science and Engineering, of the University of Toronto, in Toronto, Ont., Canada, Brig.-Gen. Charles Hamilton Mitchell passed away on August 26, 1941, at the age of sixty-nine years. Of unusually robust physique, he had been highly active and interested in many pursuits until the summer of 1940 when his health began to fail.

Born in Petrolia, Ont., Canada, on February 18, 1872, the son of the Rev. George A. and Agnes A. (Beckett) Mitchell, Charles Hamilton Mitchell was a graduate in civil engineering of the University of Toronto in 1892, receiving the professional degree of Civil Engineer in 1898. Upon graduation he became assistant city engineer of Niagara Falls, N. Y. From 1894 to 1901 he served as city engineer of Niagara Falls, Ont., at the same time maintaining a private practice in hydraulic engineering, which brought him a wide reputation as a specialist in this field and led to his appointment, in 1901, as principal assistant engineer of the Ontario Power Company. He occupied this position until 1906 when he went to Europe to investigate hydroelectric power practice there. On returning to Canada he practiced as a consulting engineer in Toronto, specializing in hydraulic and hydroelectric work, involving the design and construction of plants in the Maritimes, Ontario, and the Canadian West.

During 1909 and 1910 he was consulting engineer for the Ontario Power Company on its extension. From 1911 to 1914, and again from 1919 to 1920, he was consulting engineer of the Water Power Branch of the Federal Department of the Interior. Very frequently he was engaged as an arbitrator or expert witness in technical and legal cases.

Long before the outbreak of the first World War, military activities had claimed much of his attention. On the outbreak of that conflict he was a Major in the Corps of Guides and District Intelligence Officer on the General Staff of Military District No. 2, with headquarters at Toronto. For five years he served in France, Belgium, and Italy on the General Staff. In 1914 and 1915 he was a Lieutenant-Colonel in the First Canadian Division under Lord Byng; in 1915 and 1916 he was Chief of Intelligence for Lord Plumer, Commander of the Imperial Second Army; and in 1917 and 1918 he held the same post under Lord Cavan, at general headquarters of the British Army in Italy. In 1919 he was promoted to the rank of Brigadier-General and attached to the Intelligence Staff of the British War Office in London. Four governments honored him with decorations, and he was mentioned seven times in dispatches.

During the present war he gave valuable service as a civilian to the military authorities in connection with important matters of intelligence, and only his age prevented him from taking a more active part.

---

[1] Memoir prepared by C. R. Young, M. Am. Soc. C. E.

Upon returning from the first Great War in 1919, he was appointed Dean of the Faculty of Applied Science and Engineering of the University of Toronto, a post that he filled until his retirement on June 30, 1941. In this position he was able to maintain active and enthusiastic contact with young Canadian engineers in training, a task which he found greatly to his liking. Following his retirement he was made Dean Emeritus of the Faculty, an honor which he did not live long to enjoy.

In 1920 General Mitchell was appointed a member of a Royal Commission to report on radial railways in Ontario, and in 1924 he became a Canadian member of the International Joint Board of Engineers to study and report on the navigation and power problems of the St. Lawrence River.

An honor in which he took great pleasure came to him in 1929 when he was elected President of the Engineering Institute of Canada. He had been elected the first President of the Ontario Association of Professional Engineers in 1922. He was a member of the Board of Governors of the University of Toronto from 1913 to 1919, and President of the Toronto Board of Trade in 1927 and again in 1933.

General Mitchell occupied a highly active and influential position in the public life of Canada. The wide expressions of appreciation of his genial personality, and of his contribution to engineering and to engineering education, that have been voiced indicate general acknowledgment of the value of his services to his country.

In 1901 he was married to Myra E. Stanton in St. Catherines, Ont. Mrs. Mitchell survives him.

General Mitchell was elected an Associate Member of the American Society of Civil Engineers on June 4, 1902, and a Member on January 5, 1904.

ALFRED MITTON MOSSCROP, M. Am. Soc. C. E.[1]

DIED MARCH 27, 1941

Alfred Mitton Mosscrop was born in Brooklyn, N. Y., on January 23, 1865, the son of Thomas and Emma (Mitton) Mosscrop. He attended the public schools of Brooklyn and studied at the Brooklyn Polytechnic Institute for one year. He then entered Cornell University, at Ithaca, N. Y., from which he was graduated in June, 1885.

After his graduation from Cornell he was assistant office engineer with the Missouri Pacific Railroad Company in Kansas in 1886. He returned to Cornell University as instructor in the College of Civil Engineering from November, 1886, to July, 1887. In 1887 he began work as an assistant in the office of the Rochester Bridge and Iron Works at Rochester, N. Y., and in 1889 was made engineer of the company in charge of the city office, covering the estimating and contracting departments. For part of the years 1892 and

---

[1] Memoir prepared by Edwin A. Fisher, Hon. M. Am. Soc. C. E.

1893 he was chainman and topographer for the State of New York in the Adirondack Survey.

From 1900 to March, 1902, he was engineer and manager of the Rochester Works, then owned by the American Bridge Company. He was vice-president and manager of the Baltimore Bridge Company at Baltimore, Md., from April, 1902, to July, 1903.

In August, 1903, he became manager of the Bridge Department, Dorman Long and Company, Ltd., of Middlesbrough, England. From April, 1905, to June, 1909, he was general manager of the same company in the Rolling Mills Open Hearth Plant and Bridge Department. He was elected a director of the company in 1907. From July, 1909, to May, 1914, he was a director of the Dorman Long and Company, Ltd., with residence in the United States, where he looked after company interests. During this period he resided in Rochester. From July, 1909, to July, 1914, he was active as a consulting engineer, dealing mainly with reorganization problems for foreign bankers.

At the outbreak of the World War in 1914, he became active in Red Cross activities, giving up all other work. From March, 1918, to February, 1919, he was production manager of the Rochester District Ordnance Department, U. S. Army. From February, 1919, to about one week before his death on March 27, 1941, he was semi-retired, devoting time to the study of economic problems and giving opinions concerning them from time to time.

His chief fields of work during his active life were bridges and the operating end of rolling mills and open-hearth practice. His most important accomplishments were the reorganization, from an operating standpoint, of the Rochester plant of the American Bridge Company; the Baltimore Bridge Company; bridge shops; and the rolling mills and open-hearth plant of Dorman Long and Company, Ltd.

Mr. Mosscrop's professional standard was of the highest and best. In his business relations he had the complete confidence of all his associates. He enjoyed the respect and confidence of the community in which he lived, as a gentleman and a scholar.

He was a charter member of the Rochester Engineering Society in 1897, and of the Rochester Section of the American Society of Civil Engineers in 1923. He was also a member of the Iron and Steel Institute of England; the Military Order of the Loyal Legion in England; the Engineers Club of New York City; the Genesee Valley Club; Country Club of Rochester; and the honorary fraternity of Sigma Xi.

He is survived by his wife, the former Linnie Gambee of West Fayette, N. Y., to whom he was married on September 19, 1888. A son, Roger Gambee Mosscrop, and a daughter, Alfreda Mosscrop, also survive him.

Mr. Mosscrop was elected a Junior of the American Society of Civil Engineers on May 4, 1887; an Associate Member on May 3, 1893; and a Member on October 4, 1899.

EARLE DAWSON PARKER, M. Am. Soc. C. E.[1]

DIED JANUARY 9, 1942

Earle Dawson Parker was born on November 27, 1888, at Paris, N. Y., the son of the late Frank Parker and Julia (Morse) Parker.

After completing his course in the Sidney High School, at Sidney, N. Y., in June, 1907, he entered Rensselaer Polytechnic Institute at Troy, N. Y., and was graduated in 1911 with the degree of Bachelor of Science in Civil Engineering. At intervals during his college course Mr. Parker worked in survey parties for the New York State Highway Department, and after graduation was employed for about six months by the Public Service Commission, First District, New York, N. Y.

In June, 1912, he entered the employ of the New York State Highway Commission, and continued work for this Commission until April, 1922. He was promoted in regular steps to responsible charge of various types of highway construction and location.

In April, 1922, he entered the organization of the Lane Construction Corporation of Meriden, Conn., one of the larger contracting companies doing street and highway construction in the North Atlantic States. His advancement was consistent, and he rose to the position of assistant district engineer. In December, 1926, he became district engineer and was in charge of estimating cost, and had general supervision, of construction of highways, streets, and bridges, and structures incidental thereto, in New York and Connecticut. This included the development and assignment of construction organization, layout of plant setup for production and manipulation of all types of material, and selection and operation of appropriate transportation and performance facilities. His keen analysis of cost was particularly successful, covering an average estimate for successful bidding of more than a million dollars per year.

Contracts completed under Mr. Parker's direction were the grade-crossing eliminations in New York State at Newburgh, Chester, Cornwall, and Monroe, and dual reinforced-concrete pavement in Connecticut at East Hartford and South Windsor.

Mr. Parker's death was caused by an automobile accident on January 5, 1942, while driving from his home at Meriden to supervise construction work in New York State. He died on January 9 in the Sharon, Conn., Hospital.

He was a member of the First Methodist Church of Meriden, the Ancient Free and Accepted Masons, and the Connecticut Society of Civil Engineers.

On September 24, 1914, he was married to Grace Beagle, who survives him. One brother, Cecil M. Parker, also survives him.

Mr. Parker was elected an Associate Member of the American Society of Civil Engineers on July 9, 1923, and a Member on January 13, 1930.

---

[1] Memoir prepared by George E. Smith, M. Am. Soc. C. E.

CHARLES HOWARD PAUL, M. Am. Soc. C. E.[1]

DIED OCTOBER 6, 1941

Charles Howard Paul was born on the rock-bound New England coast at Rockport, Mass., on March 10, 1875. His father, Howard H. Paul, was a paint manufacturer and son of a ship carpenter. His mother, Lucy (Dousett) Paul, was a direct descendant of Richard Tarr, one of two shipwrecked mariners who founded Rockport about 1690. The stability and ruggedness of these ancestors and of the surroundings in which they lived seem to have been distinctly reflected in the character of Mr. Paul.

While his boyhood was not devoid of a desirable amount of play and enjoyment of the maritime surroundings, he learned how to work at an early age. He caught and sold fish to earn spending money and also operated a fleet of dories for fishermen and sightseers. The summers were spent at the Paul's camp on Cape Ann opposite Thacher Island where the favorite sports were swimming, fishing, yachting, etc. Encouraged by his father, he had a live interest in athletics and became proficient in such sports as football, baseball, tennis, and track events. He began playing basketball when it was first introduced. He was brought up in a New England Puritan atmosphere where one went to church and Sunday school, where sports and boisterous fun were taboo on Sundays, and when boys did not argue with their parents.

Charles Paul's education began in the grade schools of Rockport where he continued through the first year of high school. He finished high school at Malden, Mass., where the family moved in 1889. In 1892 he entered Massachusetts Institute of Technology, at Cambridge, Mass., taking up the study of civil engineering. He was an honorary member of Tau Beta Pi fraternity. At the end of his third year he was compelled to drop his college work because of his father's death. At this time it became necessary for him to support the family consisting of his mother, grandmother, and two younger brothers, two and four years old.

His first professional job was that of pipe inspector on the construction of the Rockport water works during a summer vacation. After leaving school he was employed for a short time by the Sewer Department of Boston, Mass., and then by the Massachusetts State Board of Health on surveys of the Neponset River basin. This work kept him busy for about twelve hours per day and consisted largely of carrying a stadia rod through the Neponset meadows and swamps. This was a good job for a young engineer in those days and paid $52.00 per month.

In 1896 he transferred to the Boston Metropolitan Water District, which had recently been organized. Here he worked on surveys and designs for pipe lines, reservoirs, and pumping stations. When construction started he was made inspector of pile foundations, laying of large mains, and other construction work. On this work he became acquainted with a number of outstanding engineers. These associations he appreciated more and more in later years. According to Mr. Paul's statement they were men who insisted on building safe and efficient structures and getting full value for every dollar spent.

---

[1] Memoir prepared by a Committee consisting of Walker R. Young, H. S. Morse, C. S. Bennett, and C. H. Eiffert, Members, Am. Soc. C. E.

In 1900 Mr. Paul accepted a position with the Bureau of Filtration in Philadelphia, Pa., on plans and specifications. During construction he was assigned to the Belmont plant which included a sedimentation basin, sand filters, and a reservoir. He was placed in charge of this work and on completion became responsible for its operation. The work of this bureau marked a great forward step in water supply engineering. At the time of its beginning typhoid epidemics were quite common in large cities, such as Philadelphia, Pa. With the completion of the work done at this time they became a matter of history in that city. It was here that Mr. Paul made his first acquaintance with dam and reservoir design and construction, a branch of engineering in which he became an eminent authority in later years. The following is a quotation from a letter written to him by the chief engineer when he left Philadelphia: "I have always felt that any work entrusted to your care would be executed in the same manner as though I were personally on the ground to supervise it."

In October, 1904, Mr. Paul entered the employ of the newly organized U. S. Bureau of Reclamation, the purpose of which was to design and build irrigation works in the arid West. His first assignment was on the Lower Yellowstone project near Glendive, Mont.

No doubt most of Charles Paul's friends and acquaintances would class him as quite conservative in every way. However, his start with the Metropolitan Water Board when it was first organized, his move to Philadelphia at the beginning of the work of the Bureau of Filtration, and then his change to the Reclamation Service at the time of its inception, indicate that he possessed in a marked degree the spirit of pioneering and the ability to adapt himself to new surroundings and circumstances.

While on this work Mr. Paul met Camilla M. Wheeler of Northville, Mich., who was teaching in one of the rural schools of Montana. This proved an important event in his life. Some of the trips to see her were made on horseback over a distance of 60 miles. They were married on June 19, 1907, at Northville. A few days later they returned to the Montana camp where a small cottage had been prepared for them. For 1½ years following, Mrs. Paul was one of two women residents at the camp. During this time the temperature dropped as low as 48° below zero and sometimes remained between 20° and 30° below for a week or more.

The next few years with the Reclamation Service brought a variety of experience on irrigation work, ranging from surveys through design and construction to maintenance and management of completed projects.

During the winter of 1910–1911 Mr. Paul was placed in direct charge, as construction engineer, of the design and construction of the Arrowrock Dam on the Boise River in Idaho. This was another job of pioneering as the Arrowrock Dam was to be higher than any dam built to that time. Its height, as originally planned and built, was 348.5 ft. It is of the curved gravity type, 1,100 ft long, and contains 600,000 cu yd of concrete. Excavation to bedrock reached a depth of 90 ft below the river bed. In 1938 this dam was raised to a height of 353.5 ft. On this work Mr. Paul was employed as consultant.

Because of possible contingencies that might arise in connection with abutments and foundations due to the unusual height of the dam, this work was done by force account rather than by contract. The organization was highly successful and the dam was completed one year ahead of schedule at a cost about 20% below the official cost estimate. It was a notable accomplishment. Mr. Paul, together with members of his organization, was commended highly by officials of the Reclamation Service and by the engineering profession.

In the fall of 1915 Mr. Paul joined the staff of The Miami Conservancy District, a political subdivision of the State of Ohio organized for flood control in the Miami Valley. Here again he joined in an undertaking which was of a pioneering nature. The method of flood control by a combination of retarding basins and channel improvements was radically different from anything previously attempted.

This project was ready for construction in 1917 when the world was in a turmoil. Because of war conditions and uncertainties it was impossible to secure reasonable bids from contractors for quantities such as were involved here. It was decided, therefore, to develop a construction organization to do the work by force account. The experience gained by Mr. Paul at Arrowrock was of great value in perfecting this organization. He soon became assistant chief engineer and in 1921 was made chief engineer of this organization. This work, which was estimated to cost more than $30,000,000, was completed below the cost estimate and ahead of schedule.

In 1924 Mr. Paul resigned as chief engineer of the Miami Conservancy District, but was retained as consulting engineer until his death. Before he left the District several floods occurred in the Miami Valley which were of sufficient magnitude to demonstrate the efficiency of the flood control works. Everything functioned as planned and there was great public interest particularly in the action of the dams.

At this time Mr. Paul established a consulting office in Dayton, Ohio, which he continued until his death.

In 1924 he managed successfully the International Air Races which were held in Dayton under the sponsorship of a large group of citizens, with the cooperation of officers of the U. S. Army Air Corps at Wright Field.

The following year he was made Managing Director of the Dayton Industrial Association. The purpose of this organization was to make a study of the local industrial situation, to act as a clearing house for local industrial problems, and to furnish authentic information to outside industries seeking a location. Mr. Paul managed this successful organization for about six years. He resigned in 1931 because of the demands on his time in other fields. From this time on he devoted practically his entire time to consulting work on large projects. The list of these is so extensive that only the principal ones will be mentioned here.

In 1933 he was appointed by the Secretary of the Interior as a member of the committee charged with the task of exploring the water problems of the

Mississippi Valley. This committee published a report in 1934 which was in popular form and was well received. From 1933 to 1940 Mr. Paul and his associates on this work passed on more than 3,000 proposed projects. Of course many of these had little or no merit but it was nevertheless necessary to give them consideration. This work later broadened into general consulting service for the Public Works Administration (PWA) and for the National Resources Board and led to the renewal of many old friendships and the making of new ones.

In 1933 he was appointed as one of the consulting engineers for the newly organized Tennessee Valley Authority (TVA). On this work he was connected with the design and construction of all the large dams built by the Authority. Most of these are outstanding in some particulars. Here also he renewed associations with many old friends, a number of whom had been his former employees and assistants.

In 1934 he was appointed as chairman of the consulting board for the Grand Coulee Dam and continued on this work until his death. This is the largest concrete dam in the world and probably the largest concrete structure of any kind ever built. During the years following this appointment he acted as consultant on many other dams of the U. S. Reclamation Bureau and served as chairman of the consulting board on a number of these projects. Among them were the Central Valley project of California, Marshall Ford Dam in Texas, Seminoe Dam in Wyoming, Bartlett Dam in Arizona, Deer Creek Dam in Utah, Green Mountain Dam in Colorado, and the inspection of many other dams and dam sites. Altogether he had an important part in the design, construction, or inspection of more than 200 dams, both earth and concrete. This work was located in 34 of the States. He had an unusually broad experience in the investigation, study, and treatment of dam foundations.

Mr. Paul always took an active part in civic and community affairs. At the age of 22 he was elected a member of the City Council of Malden. He was active in the Young Men's Christian Association (Y. M. C. A.) whenever he was so located that this was possible. At Dayton he was a member of the board of trustees and the advisory council of that institution for many years. In 1933–1934 he served as president. He served as a director of the Dayton Community Chest from 1927 to 1939. He was a member of the Chamber of Commerce for many years and also served as a director. In 1924 he became a member of the Dayton City Plan Board; and in 1925, at the request of a number of prominent citizens, he became a candidate and was elected to the City Commission, which is a non-partisan legislative and advisory group at the head of the Dayton Commission-Manager government. He served in this capacity for 4 years, during which several major projects were initiated in Dayton. During his service with the Dayton Industrial Association, which has been previously mentioned, he selected the site and directed the acquisition of the land for the Dayton Municipal Airport. In the years 1924–1926 he was a member of the building committee of Westminster Presbyterian Church and later of a similar committee for the new Y. M. C. A. building. Each of these structures was valued at about $1,000,000. He was a member of the Rotary Club of Dayton until his work took him away from Dayton too often.

One of Mr. Paul's outstanding characteristics was his ability to make friends, not only in the engineering profession but also among those with whom he associated in his daily community life. This applied to young men in minor positions as well as to persons of higher rank. Many of his assistants and subordinates, and others not directly connected with his work, were guided by the friendly counsel and advice which he was always ready and willing to give.

He was the author and co-author of many reports, articles, and papers published in engineering magazines and periodicals. In addition, he wrote a number of chapters for technical books.

Mr. Paul was one of the early presidents of the Engineers Club of Dayton, and of the Technology Club of Dayton. He was one of the organizers and the first president of the Dayton Section of the American Society of Civil Engineers. In 1922 he was awarded the Norman Medal of the Society for his paper entitled "Core Studies in the Hydraulic-Fill Dams of the Miami Conservancy District."[2] From 1924 to 1928 he served as a Director of the Society. During that time he served on a number of important committees including those on Flood Protection Data, Reorganization of Government Departments, Public Relations, Technical Activities and Publications, Aims and Activities, Professional Conduct, Technical Procedure, and Technical Expansion. He also contributed several technical papers and numerous discussions to the publications of the Society and was awarded Life Membership in 1940.

Mr. Paul is survived by his widow, and two brothers, Edwin L. and Elliot H. Paul.

Mr. Paul was elected an Associate Member of the American Society of Civil Engineers on June 7, 1905, and a Member on September 1, 1908.

ROBERT JUSTICE PAULETTE, M. Am. Soc. C. E.[1]

Died August 28, 1941

Robert Justice Paulette was born at St. Joseph, Mo., on June 2, 1886. He was the son of Charles T. and Alma (Wilson) Paulette. He attended the public schools of St. Joseph and was graduated from the University of Missouri, at Columbia, in 1912 with the degree of Bachelor of Science in Mining Engineering. He received the degree of Civil Engineer from the same University in 1932.

Mr. Paulette was early attracted to engineering and spent his summer vacations, while attending high school, with surveying parties in and around St. Joseph. During his vacations, while in the University, he worked at various times for the St. Joseph-Southern Railway Company, the City of St. Joseph, and The Home Telephone Company.

He spent the two years following his graduation with the Anaconda Copper Mining Company at Great Falls, Mont. This engagement was followed by two years with the U. S. Reclamation Service on the Sun River Project at Fort Shaw, Mont.

---

[2] *Transactions*, Am. Soc. C. E., Vol. LXXXV (1922), p. 1181.

[1] Memoir prepared by Lloyd B. Smith, M. Am. Soc. C. E.

In 1915 Mr. Paulette became construction engineer for Black and Veatch, Consulting Engineers, in Kansas City, Mo. Then in 1917 he entered the armed forces of the United States as First Lieutenant of the 315th Engineers and two years later returned from overseas as Captain with the 513th Engineers.

In 1925, after serving the City of Emporia, Kans., for five years as city engineer and superintendent of utilities, he became director of public works for the City of Salina, Kans.

In 1931 he went into private consulting engineering practice and a year later organized the Paulette and Wilson Engineering Company. He remained active in this organization until his death. For two years during this time, 1933 to 1935, however, he retired from the company to act in the capacity of state engineer, Federal Emergency Administration of Public Works.

The engineering work of Mr. Paulette extended into a wide variety of fields. He handled the many heavy responsibilities that fell to him with engineering exactness and efficiency, with fairness to all, and with unusual satisfaction to his clients and employees.

He was active in the passage of the Engineer's Registration Law in 1931. He was appointed a member of the first Registration Board of Professional Engineers and was elected secretary of the Board, which office he held until his death. This indicates the high regard in which he was held, not only by the engineers of the state but by the general public, since the appointing authorities changed political parties during the time of his incumbency.

Mr. Paulette took an active part in the various engineering organizations. He was past-president of the Kansas Water and Sewage Works Association and a member of the Kansas Engineering Society, the Topeka Engineers Club, and the American Water Works Association.

He was married to Jessie A. Griebie at Farmington, Minn., on August 24, 1917. He is survived by his widow and three children, Grace Alma (Mrs. D. V. McClure); Robert Griebie Paulette, Jun. Am. Soc. C. E., Second Lieutenant, U. S. Air Force; and Charles Harvey Paulette.

Mr. Paulette was elected a Member of the American Society of Civil Engineers on November 15, 1926.

RAYMOND ALBERT PEASE, M. Am. Soc. C. E.[1]

Died April 19, 1941

Raymond Albert Pease was born at Kelso, N. Dak., on June 19, 1888, the son of Albert Edward Pease and Jennie (Files) Pease, pioneers in North Dakota. He received his elementary education at Kelso, attended Central High

---

[1] Memoir prepared by Z. E. Sevison, M. Am. Soc. C. E., and Ray Robinson, Maintenance Engr., North Dakota State Highway Dept., Bismarck, N. Dak.

School in Minneapolis, Minn., and was graduated in 1908. He then entered the University of Minnesota, at Minneapolis, receiving the degree of Bachelor of Science in Civil Engineering in 1912 and a degree in Civil Engineering in 1913. While a student there, he became a member of Psi Chapter of Theta Xi, engineering fraternity.

Mr. Pease began his professional work in September, 1913, as instrumentman and draftsman with B. J. Reynolds, at Redwood Falls, Minn. From June, 1914, until November, 1915, he held the position of assistant city engineer, City of Chisholm, Minn. From June, 1916, until September, 1917, he served as deputy county surveyor, Ward County, North Dakota. At that time he entered the United States Army, serving as a Private, Corporal, and then Sergeant in the 313th Engineers, and as 2d Lieutenant in the 29th Field Artillery.

Following his service in the U. S. Army, Mr. Pease resumed his position as deputy county surveyor of Ward County in April, 1919, and served in this capacity until May, 1921. In July, 1921, he became a resident engineer for the State Highway Department. He held this position until September, 1925, when he became division engineer of the Minot Division of the North Dakota State Highway Department. He continued in this position until June, 1933.

Mr. Pease was camp superintendent of Civilian Conservation Corps (CCC) camps and was in charge of parties on survey and design of water conservation dams, serving under A. D. McKinnnon, coordinator of the Federal Soil Conservation Service, at Bismarck, N. Dak., from June, 1933, to December, 1934. From April, 1935, until June, 1935, Mr. Pease was assistant civil engineer with the Bureau of Biological Survey. He then became resident engineer inspector for the Public Works Administration (PWA). He resigned from this position in February, 1940, when his health failed.

Besides his membership in the Society, Mr. Pease was a member of the Society of American Military Engineers. He was licensed in the State of South Dakota as a professional engineer and land surveyor. Mr. Pease was active in the community life of his home city of Minot, N. Dak., being a member of the American Legion, Veterans of Foreign Wars, and the Lions Club.

He was ever alert to promote the interests of good roads and water conservation in Minot and in the whole northwestern North Dakota area. He was of unassuming nature and not many knew of his assistance to young men, particularly those interested in engineering, in completing their college education when their parents were unable to give financial assistance. As a tribute to his memory, immediately following his death, friends in Minot collected a considerable sum of money as a contribution to the Children's Home in Fargo, N. Dak. It was from this home that Mr. and Mrs. Pease adopted their infant son, Theodore, in 1930.

On May 7, 1922, Mr. Pease was married to Laurel Vivian Alpstag, who, with their son, survives him.

Mr. Pease was elected a Member of the American Society of Civil Engineers on August 17, 1931.

JOHN JOSEPH PHELAN, M. Am. Soc. C. E.[1]

Died February 11, 1941

John Joseph Phelan was born in Lowell, Mass., on April 28, 1879, the third of four children born to Arthur Quin and Mary Ann (Molloy) Phelan. His father was a physician, having received his degree in medicine at Harvard University, Cambridge, Mass., after his earlier studies at Dublin College, Ireland. His mother and sister were graduate practicing pharmacists.

As a youth Mr. Phelan received his primary and high-school education in Lowell. Even at an early age he showed a deep interest in military training and ranked as a first lieutenant in his high-school battalion. His histrionic flare found expression in amateur school and college theatricals as minstrel end man, as comedian in musical comedy and light opera performances, as drummer in the college band, and with the glee club at college as bass and soloist, as well as in the church choir. This was a direct inheritance from his mother's brother, Terrence Molloy, a great tenor singer and church organist, who was cast in a stage play with the well-known Raymond Hitchcock.

He was graduated from the Lowell High School in 1898 and employed by "The Proprietors of the Locks and Canals" on the Merrimack River, at Lowell, as hydraulic engineer on water and mill maintenance until 1903. He attended Tufts College, at Medford, Mass., from which he received the degree of Bachelor of Science in Civil Engineering in June, 1907. During two summers of his college years (1905 and 1906), he was employed by the New England Telephone and Telegraph Company as assistant to the division chief inspector in Lowell, assigning work to forty-five inspectors and instrument-men, while engaged in making payrolls, writing checks, and accounting for stock supplies.

For the next three years (until 1910) Mr. Phelan was engaged in triangulation, surveying, and chart making of the waters of Chesapeake Bay and tributaries with the United States Coast and Geodetic Survey in cooperation with the Maryland Shell Fish Commission on oyster bar survey. This work included the navigation and thorough knowledge of these waters, as well as the maintenance of steam, gasoline, and kerosene oil boats.

For the next year until May, 1911, he was with the United States Geological Survey as hydraulic engineer in the Water Resources Branch on stream gaging and surveys in the Adirondack Mountains in New York State and office work in Washington, D. C.

His next engagement (May, 1911, to December, 1917) was with the International (Canadian) Boundary Commission. The last four of these years he was chief of party, establishing and marking the United States-Canadian boundary between Minnesota and Ontario, working in topography, astronomy, triangulation, leveling, and disbursements and subsistence supply for a topographic and leveling party of thirty men and a monumenting and referencing party of ten men.

---

[1] Memoir prepared by Lynn Perry, M. Am. Soc. C. E.

When the United States entered the war in April, 1917, Mr. Phelan applied for a commission, and on June 19, 1917, was commissioned Captain in the U. S. Army Engineers, but was not released from his work with the Boundary Commission until December. On December 14, 1917, he was assigned by the War Department to military mapping in Virginia and Georgia and later as an instructor in Astronomy, Geodesy, Topography, Hydrography, Photography, and Map Reproduction in the Regular Army Post-Graduate Engineer School, Camp Humphreys (later Fort Belvoir), Virginia.

Being discharged from the Army on October 31, 1919, Captain Phelan was employed until July, 1920, as civil engineer and principal civilian assistant to the Constructing Quartermaster and Utility Officer on Construction and Operation of hospital buildings. He was placed in charge of design and construction of buildings, highways, utilities, and power plant at Walter Reed, United. States Army General Hospital, Washington, D. C. He was commissioned Major, Engineer Reserves, U. S. Army, on May 1, 1920.

Major Phelan was employed from August, 1920, to September, 1922, by the Federal Board for Vocational Education and its successors, the United States Veterans' Bureau and United States Veterans' Administration, in New York, N. Y., Newark, N. J., and Hartford, Conn., as vocational adviser in the rehabilitation of veterans and the preparation of appeals, and as Sub-District Manager.

He received his commission as Lieutenant Colonel, Engineer Reserve, U. S. Army, on December 1, 1923.

From September 1, 1922, to January, 1924, he was on the Board of Registration for the U. S. Veterans' Bureau, and U. S. Veterans' Administration, and from then until August, 1933, was civil engineer, Construction Division, with headquarters in Washington, D. C. On this assignment he was engaged in hospital design, construction and inspection, surveys, and maintenance of Veterans' Hospitals. Colonel Phelan also completed special assignments from the office of the Director and Administrator and for the Federal Board of Hospitalization on new hospital projects, inspections and investigations as well as selection, acquisition, title searches, and condemnation of Veterans' Hospital and Home sites. During these years Colonel Phelan's work carried him into most of the forty-eight states, and he made a host of friends wherever he went.

Because of close contact with legal matters and proceedings which his work entailed, he attended evening classes whenever he had the opportunity at the Columbus University Law School in Washington, D. C., to increase his efficiency in his work. As a result Colonel Phelan received the degrees of Bachelor of Laws in May, 1928, and Master of Laws and Master of Patent Law in June, 1930, from the Columbus University. He was admitted to the Indiana State Bar in March, 1930, and to the Supreme Court of Appeals of West Virginia as a Visiting Attorney in April of the same year.

From August to December, 1933, he was employed as Regional Utility Officer, in charge of water supply, sewage disposal, and the utilities and service employees of the United States Veterans' Hospital at Lyons, N. J.

Colonel Phelan was then appointed regional engineer in charge of engineering and inspection of field work, of relief and construction, for New England, Florida, and the Great Lakes states, also work in Washington, D. C., with the United States Civil Works Administration and Federal Emergency Relief Administration, in which capacity he served until July, 1934, when he was made inspection engineer of construction, and of the construction and space surveys of federal buildings, with the Public Works Branch of the Procurement Division, Treasury Department.

In July, 1936, he accepted the position of Utility Officer at the United States Veterans' Administration Facility, Mount Alto Hospital, in Washington, D. C., in charge of the utilities, maintenance, construction, and service employees of this hospital.

Though he had received a "certificate of capacity" for the rank of Colonel, Corps of Engineers Reserves, July 19, 1927, he was not appointed until March 12, 1936. Colonel Phelan was then assigned commanding officer of the 376th Engineers Regiment. He was very active in army reserve work (including the monthly problems) and looked forward to his yearly training periods at Fort Belvoir where he was in full command of all reserve officers in camp during his last detail there in August and September, 1939.

In April, 1938, Colonel Phelan was transferred to the United States Veterans' Administration Hospital at Wichita, Kans., in the capacity of utility officer, in charge of hospital maintenance and operations. Previously he had been instrumental in determining the site of this hospital, and in its construction. He had many friends in Wichita, made in former years. He was well and favorably known to the entire staff at the hospital, medical and service. They were grieved at his death, after a brief illness, on February 11, 1941.

Colonel Phelan was a member of the American Society of Mechanical Engineers; the Society of American Military Engineers (Charter Member); the Washington Society of Engineers; the Reserve Officers Association; the Military Order of the World War; the Fort Stevens (Washington, D. C.) and the Thomas Hopkins (Wichita) Posts of the American Legion; the Tufts Club of Washington, D. C.; the Tau Chapter of Alpha Kappa Pi fraternity; and, formerly, the Boston Society of Civil Engineers.

He was a member of the Sacred Heart Church in Washington, D. C., and a Fourth Degree Knight of the Washington Assembly of the Knights of Columbus.

Backed by years of travel and an almost inexhaustible fund of rich and interesting experiences, Colonel Phelan was a delightful conversationalist and entertaining raconteur. His outstanding characteristics were his ready wit and contagious good humor. He was a true and loyal person, with a keen sense of justice and charity. He was thorough, accurate, trustworthy, and dependable. His standards of morals, honor, and service were high. He practiced them on a high level and insisted on the same from those over whom he had jurisdiction. Many younger men who have served under his direction are indebted to him for their training in the simple old-fashioned virtues along with the accuracy and efficiency that are too frequently considered sufficient. Colonel Phelan was a student of men and of nature. He knew human nature and the motives that inspire men to "carry on" and to see the job through to the end. The years that he spent on the Maryland Oyster Bar Survey and on the Canadian Boundary Survey provided the opportunity for a thorough acquaintance with quiet Nature which he loved so much. From this he developed a fund of knowledge which was of technical value and which furnished a basis for more sublime speculation. He was not a salesman nor advertiser in any sense. Publicity had no place in his philosophy of life. He was an engineer and a leader of men.

On November 24, 1914, he was married to Emily Wherry Matter. He is survived by his widow, his son, John Joseph, Jr., and his grandson, Joseph Michael.

Colonel Phelan was elected a Member of the American Society of Civil Engineers on November 9, 1920.

WILLIAM HALE PHILLIPS, M. Am. Soc. C. E.[1]

DIED JUNE 22, 1940

William Hale Phillips was the youngest of seven children of John Phillips and Sarah (Rhoads) Phillips. He was a native Californian, born in the San Joaquin Valley Town of Lemoore, on October 26, 1877. He attended the local schools and worked on the family farm.

At a very early age he lost both of his parents. Although provided for by his grandparents, he soon found that as far as his future was concerned he would have to think out his own plans. He never cared for farming, but a liking for mathematics, which was encouraged by his high school principal, suggested that he follow engineering as a lifework. Perhaps he realized that he needed an active outdoor vocation to keep him in health, for as a youngster he had had considerable sickness. Perhaps it was to show his people that in spite of a serious physical disability he could make good. William Phillips' right hand was missing—severed at the wrist. At all events, in the face of his elders' protests and discouragement, he held to his conviction that he could become an engineer.

In 1900 he entered the University of California, at Berkeley. After three years he went to the University of Colorado, at Boulder, where he finished his undergraduate work. It was necessary for him to find employment throughout his college years to supplement his limited resources. Later he returned to the University of California where he received the degree of Master of Science in Civil Engineering in 1905.

---

[1] Memoir prepared by John R. Cahill and H. G. Sharp, Members, Am. Soc. C. E.

As he had planned years before, most of his professional activity was in the field. His first work was with the Realty Syndicate in Oakland, Calif., on surveying, subdivision, roads, and streets. In a few years he was off to the Northwest where in Spokane, Wash., he worked with the city engineer. Later he opened an office of his own.

In Spokane he met and was married to Jane Palmer of Chicago, Ill., in 1913. They had two children, Sarah and Frank, who, with Mrs. Phillips, survive him.

For several years William Phillips followed railroad work under the late James J. (Jim) Hill,[2] F. Am. Soc. C. E., of the Great Northern Railway Company. Then he went to British Columbia, Canada, on surveys for a water project. The first World War interrupted this work so he moved to Chicago and engaged in building construction for one of the steel companies; then he went to Philadelphia, Pa., on similar work for the U. S. Navy. After the Armistice in 1918 he returned to California and opened an office in San Francisco. Later he entered the office of the state architect at Sacramento to superintend the construction of schools and hospitals. Among these were the Teachers College at Chico, The State Hospital at Ukiah, and others.

During the 1920's and 1930's he worked for contractors, engineers, and architects. For several years he was with Weeks and Day, Architects, and later with Cahill Brothers, General Contractors. He also worked for the late A. J. Cleary, M. Am. Soc. C. E., and associates on investigation and study of water resources for the San Francisco Bay area.

In 1937 he entered the employ of the San Francisco Bay Exposition where he remained during the construction period of the Fair. He left in 1939 to accept a position with the Work Projects Administration which was helping to finance the construction of school buildings. This work took him to Sonora, then to Los Angeles, and later to Redding, Calif. He was active until his death in June, 1940.

William Phillips loved the outdoors and chose his work accordingly. He was also a home-loving man and spent what time he could with his family, working in his home or in his garden, for one of his hobbies was flowers. He was always interested in boys, and in his later years he gave much time to boys' welfare work, actively serving the local Boy Scout Troup as committeeman. His passing is a real loss to the profession and to the community.

Mr. Phillips was elected a Junior of the American Society of Civil Engineers on November 1, 1904; an Associate Member on May 4, 1909; and a Member on May 15, 1917.

JOHN HORTON POPE, M. Am. Soc. C. E.[1]

DIED JULY 26, 1941

John Horton Pope was born at Pomeroy, Ohio, on December 16, 1866, the son of the late Maj. Gen. John Pope and Clara Pomeroy (Horton) Pope.

---

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. LXXXI, December, 1917, p. 1829.

[1] Memoir prepared by F. H. Pope, Brigadier General, U. S. Army (*Retired*), Washington, D. C.

After attending schools at Fort Leavenworth, Kans., where his father was stationed, he entered Washington University, St. Louis, Mo., from which he was graduated in 1888 with the degree of Civil Engineer. For some months thereafter he was engaged in railroad surveying in Kansas.

From 1889 to 1894 he was employed by the American Bridge Company on the new Merchants Bridge at St. Louis, which was completed in the latter year. During the next three years, he was engaged on several bridge constructions, including service at Phoenixville, Pa.

In 1897 he was appointed bridge engineer of the Missouri, Kansas and Texas Railway Company, with station in Parsons, Kans., where he remained until 1902. Then he went to Manila, Philippine Islands, to do construction work on sea-wall and harbor improvements.

In 1906 Mr. Pope entered the employ of the Pearson-Farquhar Syndicate, which had large and diversified interests in Central and South America. His activities took him to Guatemala, Costa Rica, and Nicaragua. In 1908 he made a survey for the construction of the Madeira-Marmoré Railway, from the headwaters of the Amazon in Brazil to the west coast of South America. On this trip he was stricken with black-water fever, from which he never fully recovered.

He served in Bolivia with the Pearson-Farquhar Syndicate until 1913, when he was sent to Montevideo, Uruguay, to be the South American engineering representative of the Syndicate. The effect of the World War forced the Syndicate into liquidation, but he remained in Uruguay as its representative until its affairs were finally settled in 1920.

He then returned to the United States and retired from the active practice of his profession. He resided in Philadelphia, Pa., from that time until his death.

In 1897 he was married to Hope Cox, daughter of the late Jacob D. Cox, who was a Major General during the Civil War, later Governor of Ohio, and Secretary of the Interior in the cabinet of President Ulysses S. Grant. She predeceased her husband.

Surviving Mr. Pope are his sister, Lucretia Pope, and two brothers, Horton Pope, and Brig. Gen. F. H. Pope, U. S. Army (*Retired*).

Mr. Pope was elected a Member of the American Society of Civil Engineers on December 7, 1904. He became a Life Member in 1937.

JOSEPH HYDE PRATT, M. Am. Soc. C. E.[1]

DIED JUNE 2, 1942

Joseph Hyde Pratt was born in Hartford, Conn., on February 3, 1870, the son of James Church and Jennie A. (Peck) Pratt. He was educated at the Sheffield Scientific School of Yale University in New Haven, Conn., from which he received the degrees of Bachelor of Philosophy and Doctor of Philosophy in 1893 and 1896, respectively. He also received an honorary degree of Master of Arts in 1923. He was instructor in mineralogy at Yale University from 1895 to 1897, and at Harvard University, in Cambridge, Mass., during the summer of 1895.

---

[1] Memoir prepared by T. F. Hickerson, M. Am. Soc. C. E.

In 1892 Mr. Pratt went to North Carolina on his vacation to collect minerals with State Geologist Joseph A. Holmes. In 1897 he returned as a permanent citizen of North Carolina, and made his home at Chapel Hill, where he lived for forty-five years. His was an active and useful life in which he won distinction as a geologist, engineer, soldier, and all-round public servant. He lectured on mineralogy at the University of North Carolina, at Chapel Hill, from 1898 to 1901, was state mineralogist from 1897 to 1906, state geologist and director of the North Carolina Geological and Economic Survey from 1906 to 1924, and professor of economic geology at the University of North Carolina from 1904 to 1925.

Professor Pratt aided in the discovery of several Carolina minerals—pirssonite, wellsite, rhodolite, and mitchellite. He also helped to organize Western North Carolina, Inc., the Made-in-Carolina Association, and a number of civic organizations.

Interested in good roads, he was one of the pioneer advocates of better roads in North Carolina and the remainder of the United States. For ten years or more prior to the establishment of the North Carolina Highway Commission, of which he was the first secretary, he conducted an extensive educational program throughout the state, consisting of lectures and informative articles on methods of road building and the advantages of better roads. He served for years as secretary of the North Carolina Good Roads Association, conducted road institutes, and sponsored field demonstrations of road location, construction, and maintenance. He was a prominent member of the Southern Appalachian Good Roads Association and the American Road Builders Association, and was a director of the American Association for Highway Improvement.

Many other activities allied to the development of North Carolina claimed his attention. He was at one time the president of the American Peat Society; a member of the National Association of Shell Fish Commissioners, the National Drainage Association, the North Carolina Drainage Association, the Forestry Congress (South), the American Chemical Society, the American Association for the Advancement of Science, the American Institute of Mechanical and Metallurgical Engineers, the North Carolina Academy of Science, and the Fisheries Society; chairman, executive committee of the Appalachian Press Conference; past secretary, North Carolina Fisheries Association; and director of the American Forestry Association, the National Parks Association, and the Military Engineers Society.

At the St. Louis (Mo.) Exposition in 1904, he was a member of the international board of awards. In 1907 he was chief of the Department of Mines and Metallurgy at the Jamestown (Va.) Exposition. From 1904 to 1905 he was expert, Twelfth United States Census on asbestos, etc., for the U. S. Coal Testing Plant at St. Louis. He contributed many articles to scientific magazines, both domestic and foreign, on mineralogical, geological, and chemical subjects. Among his later publications were articles entitled "Topographical Mapping" and "American Meridians."

When America entered World War I, Joseph Hyde Pratt was commissioned Major in the 105th Regiment of Engineers of the North Carolina National Guard in the 30th ("Old Hickory") Division. He was promoted to Lieutenant Colonel in November, 1917; went to France in the summer of 1918; served in Flanders and Belgium, and in the Somme offensive as commander of the regiment; and was commissioned Colonel in October, 1918. It was the 30th Division which made the first big break in the Hindenburg line, and Colonel Pratt received the Distinguished Service Medal in recognition of his services in that and other operations. His War Diary, consisting of a series of daily letters to his wife and son during the period May, 1918, to May, 1919, was published in book form by Colonel Pratt in collaboration with the North Carolina Historical Commission.[2]

After the war he returned home with impaired health, which caused his retirement to the hospital for about three years. He was unable to take up again all the former connections with the North Carolina Geological Survey, and so he decided to resign this position in 1924. Later, with improved health, he served as regional engineer of the Civil Works Authority, the Federal Emergency Relief Administration, and the Resettlement Administration; still later he was contact engineer for the Work Projects Administration. For a time he was senior engineer consultant for the U. S. Geological Survey.

As one of North Carolina's most prominent civic leaders, Colonel Pratt was president of the North Carolina Symphony Orchestra Society, president of the North Carolina Society for the Preservation of Antiquities, chairman of the Chapel Hill chapter of the Red Cross, and chairman of the Orange County Welfare Committee. Declared Chapel Hill's "most valuable citizen" in 1940, he was presented with the annual award for his work in local welfare groups and for establishment of the negro community center.

He was a member of the Cosmos Club (Washington, D. C.); Washington Philatelic Society; Sigma Xi; Alpha Tau Omega; and the Order of Gimghouls (Carolina). He was a member of the Episcopal Church. One of his hobbies was old stamps, of which he had a very interesting collection. Chapel Hill will long hold Colonel Pratt in grateful and affectionate remembrance.

He was married to Mary Dicus Bayley of Springfield, Ohio, in 1899, and they had one son, Joseph Hyde Pratt, Jr., a physician at the Mayo Clinic in Rochester, Minn. After the death of Mrs. Pratt, in 1929, Colonel Pratt was married in 1930 to Harriet White Peters of Baltimore, Md., and Washington, D. C. He is survived by his widow; one son; two sisters; two stepsons, James Girvin Peters and Horace White Peters; and several nieces and nephews.

Colonel Pratt was elected a Member of the American Society of Civil Engineers on June 6, 1921.

---

[2] "War Diary," by Joseph Hyde Pratt (Edwards and Broughton, publishers), Raleigh, N. C.

GEORGE WILLIAM REAR, M. Am. Soc. C. E.[1]

DIED FEBRUARY 10, 1942

George William Rear was born in Uxbridge, Ontario, Canada, on June 13, 1873. His parents were John and Mandilla (Hilborn) Rear. He received his education at Campbellford Collegiate Institute, Northumberland County, Ontario, Canada, and was graduated in 1891. He spent his vacations of 1889 and 1890 (a total of nine months) in the engineering department of the Midland Railway Company of Canada as an engineering apprentice. After his graduation from college, he was employed for four years by the Midland Railway Company of Canada as rodman, chainman, and transitman, and also worked in the office on line changes, grade revision, and bridgework.

From 1895 to 1901 Mr. Rear was with the Grand Trunk Railway Company in Canada, after it had absorbed the Midland Railway Company. He acted as draftsman, checker, inspector, foreman, and accountant, and worked on various other engineering assignments. His last work for the Grand Trunk Railway Company was as chief clerk in the office of the superintendent. While with the Canadian railways, Mr. Rear was engaged in work on surveys and construction of the bridges over the Trent, Otonabee, Moira, and other rivers, including the work of rebuilding the Victoria Bridge at Montreal, Quebec. He was also engaged on the Don improvement at Montreal and many grade improvements, including those at Trenton, Ontario, St. Annes, Quebec, and Vaudrieul, Quebec.

Mr. Rear's services with the Southern Pacific Company in the United States began on July 3, 1901, as foreman of bridge erection, and he served in this capacity until March, 1902, when he became assistant general bridge inspector. From August, 1905, until his death he was engineer of bridges (part of this time he had the title of general bridge inspector).

A complete list of the various structures that Mr. Rear designed and constructed for the Southern Pacific Lines during his long service would be too lengthy to include herein. A few of the more important ones are the Suisun Bay Bridge, California; Sacramento River Bridge at Sacramento, Calif.; and bridges over the American River, California, Colorado River at Yuma, Ariz., Wilmington Harbor, California, Los Angeles River, California, and the Willamette River and other waterways in the State of Oregon.

Mr. Rear had many friends. A fine, honest, upstanding man, he was unusually sincere in his friendships, and all who knew and worked with him loved him. His honesty, loyalty, self-sacrifice, belief in fair play, tolerance, and keen sense of humor were outstanding characteristics. His generosity and willingness to help a friend or associate in need, and his kindliness toward others, were among his finest traits. He took great pride in his profession and work.

On April 8, 1903, he was married to Madge Virginia Jackman at Santa Rosa, Calif. He is survived by his widow; a son, George W. Rear, Jr.; a daughter, Madge D. (Mrs. Robert R. Root); and a granddaughter, Geraldine M. Root. He was a wonderful husband and father.

---

[1] Memoir prepared by W. H. Kirkbride, M. Am. Soc. C. E.

Mr. Rear was very active in fraternal work, and was a life member of Royal Victoria Lodge No. 57, F. and A. M., of Montreal; a member of Park Boulevard Lodge No. 568, F. and A. M., of Oakland, Calif.; a Knight Commander, Court of Honor, Oakland Scottish Rite Bodies; Past Venerable Master, Knights Kadosh, Oakland Consistory No. 2; Senior Warden, Oakland Lodge of Perfection No. 2; and a member of Aahmes Temple, Ancient and Accepted Order, Nobles of the Mystic Shrine. He was one of the organizing members of the Pacific Railway Club of San Francisco, Calif., in 1917, and was president of the Club in 1918 and on its Board of Governors from 1918 to 1922.

Mr. Rear was a member of the American Railway Engineering Association, a member and past president of the American Railway Bridge and Building Association, and a member of the Engineers' Club of San Francisco.

He passed away in San Francisco on February 10, 1942, and the funeral services were held on February 13 at the Scottish Rite Temple, in Oakland, and were conducted by Gethsemane Chapter No. 2, Knights Rose Croix, and the Rev. J. A. B. Fry, D.D.

Mr. Rear was elected a Member of the American Society of Civil Engineers on October 15, 1923.

CHARLES RUSS RICHARDS, M. Am. Soc. C. E.[1]

DIED APRIL 17, 1941

Charles Russ Richards was born in Clarks Hill, Ind., on March 23, 1871, the son of Charles and Sarah Elizabeth (Watt) Richards. His mother was of the family that produced the famous Scottish inventor and engineer, James Watt, so it was but natural that young Richards turned to engineering as his profession.

Mr. Richards was graduated from Purdue University, at Lafayette, Ind., in 1890 with the degree of Bachelor of Mechanical Engineering. In 1891, he received the degree of Mechanical Engineer from Purdue, and in 1895 the degree of Master of Mechanical Engineering from Cornell University, in Ithaca, N. Y., doing his work *in absentia*. In his undergraduate days he was a college mate of George Ade and, together with that later famous humorist and others, he promoted Purdue's early football teams. Too small to play, he was an enthusiastic supporter and aided in the management of the team.

In 1891 he began his career as a teacher and engineer by becoming an instructor of mechanical engineering at Colorado State College of Agriculture and Mechanical Arts, in Fort Collins, Colo., where he designed the college foundry. He went to the University of Nebraska, at Lincoln, in 1892 and remained there until 1911. He spent the first two years as adjunct professor of manual training and during these two years designed and erected the college shops. During the next four years he was professor of practical mechanics. In 1898 he became professor of mechanical engineering. Nebraska's Mechanical Engineering Laboratory was designed and erected by Professor Richards. From 1907 to 1909 he served as associate dean of the Industrial College and had charge of all engineering. From 1909 to 1911 he was dean of the College of Engineering.

---

[1] Memoir prepared by Walter R. Okeson, M. Am. Soc. C. E.

During this period of nineteen years Professor Richards was active in field sports, being an ardent hunter and fisherman. Later his life became too sedentary, and his scholarly and administrative duties pushed into the background all forms of active exercise. Doubtless this immolation of outdoor recreation on the altar of duty had much to do with his subsequent breakdown while still in his early sixties.

In 1911 Professor Richards was called to the University of Illinois, at Urbana, as professor of mechanical engineering. He reorganized the system of shop instruction and designed and supervised the reconstruction of the Mechanical Engineering Laboratory. His great administrative talent was recognized, and from 1913 to 1915 he was acting dean of the College of Engineering and acting director of the Engineering Experiment Station. From 1917 to 1922 he was dean of the College of Engineering and director of the Engineering Experiment Station, and was in general charge of the original organization of the School of Military Aeronautics of the University of Illinois. When the United States entered World War I, he added to his other duties by serving on the National Committee of Coal Conservation and as consulting engineer of the U. S. Bureau of Mines.

In the fall of 1922, Dean Richards went to Lehigh University, in Bethlehem, Pa., as president. The impression he made on his fellow faculty members at the University of Illinois is evidenced by the engrossed resolution adopted and signed by his colleagues in the College of Engineering of that University. It reads as follows:

> "As you leave the University of Illinois, we wish to express the pleasure we have had in our association with you and our regret that it must be interrupted.
>
> "In our dealings with you as Dean of the College of Engineering, we have prized especially the sympathetic co-operation, the frankness and the impartiality upon which we have all come to rely. We have felt ourselves, as a faculty, safely and adequately and vigorously represented both within and without the University. We shall always remember the cordiality and sincerity that have marked our personal as well as our official relations.
>
> "We assure you of our appreciation of the important contribution you have made to the progress of the College of Engineering through the sound judgment and vision with which you have administered its affairs.
>
> "Our regret in having you go from us is tempered by our pride in your election to the presidency of Lehigh University. We heartily wish you the highest measure of success in that position, and the fullest opportunities for service and accomplishment in the years to come."

At Lehigh he began the work which will stand as a monument to one of the great educators and administrators of his day and generation. In thirteen short years he made over this institution. Under his inspiring leadership the alumni raised millions for endowment and millions more for plant, and the faculty grew steadily in teaching strength and in productive scholarship and research.

In his first year at Lehigh he made a survey of the University's needs and laid out a constructive program designed to produce a unique and outstanding educational institution. He had no patience with shirkers or those who lacked vision. Faculty members who had no desire to add to the sum of human knowledge but preferred merely to follow routine teaching methods had short shrift. Alumni who felt that winning football teams were more important than educational standards were horrified when, taking the "bull by the horns" and supported by his trustees, he abolished athletic scholarships and took the lead among eastern colleges in putting athletics at Lehigh on a strictly amateur basis. To the surprise of those who thought he was destroying alumni support and believed he would shrink student enrollment, the exact opposite happened. The enrollment of the University doubled, and the endowment and plant trebled through alumni contributions.

President Richards was an excellent business man as well as an outstanding educator. During his administration Lehigh University showed an operating surplus each year. Although the salaries of faculty members had been increased during his early years as president to a scale comparable with other first-class institutions, there was no cut in them during the depression years. By rigid economy in other directions he kept the University "out of the red."

Seldom does an institution receive such devoted service as President Richards gave to Lehigh. Every waking hour was given to thought and action that resulted in a complete reorganization of the work in the three colleges which make up the University. Administrative machinery and methods were expanded and improved. To list the results he produced in material welfare and educational improvement would take many pages. Suffice it to say that few college presidents have equaled his accomplishments.

In the summer of 1934 he was stricken with a heart attack while on a vacation in Minnesota. He was able to return to his home on the campus but never improved sufficiently to "get back into harness." In the spring of 1935 he definitely decided to resign although this move was vigorously opposed by the trustees. As always, seeing what he conceived to be his duty, he was unmoved by their protests and insisted that his resignation be accepted. No body of men ever parted from a leader with more regret than did the trustees of Lehigh University when they finally and reluctantly accepted his resignation.

It was typical of President Richards that no sooner was his resignation accepted than he began to plan to move away from Bethlehem. He loved the hills and valleys of eastern Pennsylvania, but he felt that his presence in any close proximity to the University would be unfair to his successor and might hamper that successor's administration. With him, Lehigh's welfare always came ahead of any personal pleasure or comfort. He moved to Minneapolis, Minn., to be near his daughter, Lenore, and there continued his fight to regain his health, steadily obeying—like the good soldier that he was—every mandate of his physician, even though it was torture for his active mind to be compelled to lie dormant instead of playing its usual part in the affairs of education.

President Richards was elected President-Emeritus of Lehigh University on the date of his retirement. During his presidency he had been a consulting engineer member of the Philadelphia Ordnance District and a member of the Board of Visitors of the U. S. Naval Academy. He was an active member and Fellow of the American Society of Mechanical Engineers, having been on its Council from 1918 to 1921, and a Fellow in the American Association for the Advancement of Science. He was a member of the Western Society of Engineers; the Sigma Xi honorary research society; Tau Beta Pi and Sigma Tau honorary engineering societies; Pi Tau Sigma, honorary mechanical engineering fraternity; the Sigma Chi fraternity; Omicron Delta Kappa; and Scabbard and Blade.

In 1920 he received the degree of Doctor of Engineering from the University of Nebraska. He received the honorary degree of Doctor of Laws from the following colleges: Lafayette College, at Easton, Pa., in 1922; Purdue University in 1932; University of Pennsylvania, at Philadelphia, Pa., in 1935; and Lehigh University in 1936.

On November 26, 1891, he was married to Alida Russell Beardsley at Lafayette, Ind. Of this union were born two children, a daughter, Lenore, and a son, Robert Watt. Mrs. Richards and the two children survive him.

After seven years of suffering President Richards passed away on Thursday, April 17, 1941. His body was brought to Bethlehem for interment after services in the chapel of the University he so deeply loved and so greatly served.

President Richards was elected a Member of the American Society of Civil Engineers on November 26, 1923.

HENRY CHANDLER ROBBINS, M. Am. Soc. C. E.[1]

Died May 6, 1941

It is granted to some men that they leave behind them one or more striking monuments to their skill and knowledge. To others, the opportunity to perform any single work which is outstanding does not come; but they do leave a mark in the world by doing everything that comes to their hand with care and thoroughness, no matter how unimportant it may seem. Henry Chandler Robbins was of the second group, for although there are many fine buildings through New England, in the planning and design of which he had an important part, there are none in which imposing appearance or ornamental treatment is nearly as important to the value of the building as the knowledge and care that entered into every detail.

During the earlier years of his association with the late Edward D. Densmore and Gifford LeClear, much of his work was along the lines of structural engineering, and at that time he made the structural design for one of the first large reinforced concrete buildings in the immediate vicinity of Boston, Mass., an undertaking that demanded courage as well as knowledge, for at that time the first Joint Committee had not made its report[2] and the trade still spoke of concrete buildings as "mud houses." With the passing of the years, and especially after the deaths of his partners, he was forced to give up active participation in the engineering part of his work and delegate that to others. His interest in that branch of architecture, however, never lessened and he was always ready to give an attentive ear to any proposed method of construction that gave promise of contributing to safe and economical buildings.

---

[1] Memoir prepared by Francis S. Wells, M. Am. Soc. C. E.

Henry Robbins was born in Westbrook, Me., on September 12, 1876, the son of Frederick E. C. and Elizabeth A. (Rogers) Robbins.

In 1895 he entered the employ of F. H. Fassett, Architect, of Portland, Me., remaining there until 1897 when he entered the Harvard University School of Architecture, at Cambridge, Mass., as a special student. From 1898 to 1905 he was employed by Warren, Smith and Biscoe, Architects, of Boston; and from 1905 to 1907 he was an architect in the Boston office of the American Telephone and Telegraph Company. In 1907 he made his connection with the firm of Densmore and LeClear, an association that was to prove his real life work. Prior to this time, the firm had been engaged in strictly mechanical engineering work, and was just beginning to broaden out into general architecture, the objective being to build an organization that would cover all parts of the planning of buildings, including the work they had previously done. From 1907 to 1914 Mr. Robbins was an employee; he became a silent partner in 1914; and in 1923 the firm name was changed to Densmore, LeClear and Robbins.

This was the era of prosperity for architects and, during his association with Messrs. Densmore and LeClear, many buildings were planned in which they could, and did, take genuine pride. Among them are the Paine Furniture Company Building, the Salada Tea Company Building, and the Park Square Building, all in Boston. At the time of its erection, the Park Square Building was the fifth largest office building in the world from the point of view of rentable area. Although there was no permanent agreement between the firm and the New England Telephone and Telegraph Company, Mr. Robbins and his associates did so much work for that company that many believed them to be their official architects. Of the scores of Exchange Buildings designed for that company, those at Worcester, Mass., and in Bowdoin Square, Boston, are outstanding.

He served the American Institute of Architects as a member of the Committee on Architectural Services for the two last years of his life and was Treasurer of the Boston Society of Architects in 1938 and 1939.

Mr. Robbins was elected a Member of the American Society of Civil Engineers on June 18, 1918.

---

[2] Final Report of the Special Committee on Concrete and Reinforced Concrete, *Transactions*, Am. Soc. C. E., Vol. LXXXI, December, 1917, p. 1101.

CHARLES VICTOR SEASTONE, M. Am. Soc. C. E.[1]

Died September 26, 1940

Charles Victor Seastone was born in New Boston, Ill., on April 18, 1872, the son of John August Seastone and Eva Sophia (Hjalmar) Seastone. His parents were born in Sweden, but came to the United States independently in their youth and were married in this country. His father was a manufacturer, and this early association probably influenced the son to enter the engineering profession. His early education was obtained in the public schools of New Boston.

Mr. Seastone entered the College of Civil Engineering of the University of Illinois, at Urbana, in the fall of 1889. He continued his University work until 1893 when he contracted typhoid fever. This so incapacitated him that he was obliged to discontinue his college work for a year. He reentered the University in the fall of 1894 and was graduated with the degree of Bachelor of Science in Civil Engineering in June, 1895. He early won the marked regard and respect of his classmates—regard for him personally for his intrinsic worth, and respect for his mental keenness. He was entirely free from the infirmity of self-assurance that bright young men sometimes exhibit. An able student with a high scholastic record, he had a keen analytical mind and an uncanny facility in rapid mathematical computations. It is related that, during a discussion in class as to the merits of the slide rule and the computing machine in shortening the time required for mathematical computations, young Seastone was chosen to compete with others operating these devices. On this occasion he was able to furnish the correct answers to the same problems before they were solved by the operators of the slide rule or the calculating machine.

Mr. Seastone was a classmate, and for some time a roommate, of the late Milo Smith Ketchum,[2] Hon. M. Am. Soc. C. E. During their senior year these two undertook a thesis entitled: "An Investigation of the Flow of Water through Siphons." This was a unique and outstanding piece of experimental work. They designed the test layout and erected the apparatus without assistance. Such matters as vacuum, flow, accumulation of air, length of time before cessation of flow, etc., were included in the test program under heads of from 2 to 8 ft and with lifts up to 27½ ft. The conduct of the test was very commendable.

In his early life Mr. Seastone was noted for his somewhat taciturn manner, a habit which remained with him even in the later years of his life, except among personal friends or in his professional work, where he was noted for the free, frank, and candid expression of his opinions. His early teachers at the University recall that Mr. Seastone disclosed in a marked degree what well may be called a "professional" spirit, and he was habitually a good stride ahead of his classmates.

---

[1] Memoir prepared by Daniel W. Mead, Past-President and Hon. M. Am. Soc. C. E.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 102 (1937), p. 1487.

While a student, Mr. Seastone engaged in practical engineering work during most of his summer vacations: In 1890 as an assistant surveyor in Mercer County, Illinois; in 1891 as engineer in charge of highway and levee location and construction; in 1892 as engineer in charge of levee construction; and in 1893–1894 as engineer on location of twenty units of county roads, and as assistant surveyor.

For two years after his graduation Mr. Seastone was employed by the Mississippi River Commission as assistant hydrographer in charge of instrument work. In 1897 he accepted the invitation of Prof. A. N. Talbot, Past-President and Hon. M. Am. Soc. C. E., to return to the University of Illinois as his personal assistant in charge of laboratory work in theoretical and applied mechanics (including hydraulics), where his services were reported as unusually satisfactory. He was considered an excellent teacher. He served in this position for three years, and in 1900 he went to Purdue University, at Lafayette, Ind., as associate professor of sanitary engineering under Prof. William D. Pence, M. Am. Soc. C. E., whose acquaintance he had previously made at the University of Illinois. Here he made an excellent record as a teacher and practical engineer. Upon his resignation in 1907 he gave up teaching as a career.

Professor Seastone did considerable practical work during his vacation periods. He designed the West Lafayette (Ind.) sewer system and was in charge of the design and construction of the roadway from Lafayette to the Soldiers Home and also of the relocation of the Lafayette Street Railway branch to the Soldiers Home.

In 1898 he had served as assistant engineer to the writer on the reconstruction of the Rock Island (Ill.) reservoir and slow sand filter system; and in the summer of 1900 he had served as resident engineer on the construction of a bridge over the Rock River at Rockford, Ill., also for the writer. This contact later led to many years of professional association in consulting work.

In the fall of 1906 Professor Seastone was offered the position of principal assistant engineer to the writer in his consulting office at Madison, Wis. He at first declined the appointment as he had previously agreed to continue his teaching at Purdue University for the year 1906–1907. President W. E. Stone of that institution, hearing of the opportunity, offered to release Professor Seastone from his position. He finally accepted, and began work in January, 1907. He served in this position until January 1, 1913, when he became a partner. This partnership lasted until January 1, 1933, when the business was turned over to three associates of the firm under the name of Mead, Ward and Hunt. Mr. Seastone continued as a consultant until disabled by sickness about a year before his death.

The scope and character of Mr. Seastone's experience in the course of this partnership is best indicated by brief descriptions of typical projects handled during this period. At the time that he entered the Madison office, plans for the construction of a hydroelectric plant at Kilbourn (later Wisconsin Dells), Wisconsin, on the Wisconsin River, were under way. This plant was one of the earliest of this type in the Middle West, and was built to transmit electric power at 66,000 volts to Milwaukee and Madison, Wis. The dam was built between the high sandstone bluffs of the "Dells" of the Wisconsin River where the section of the river was sufficient only for flood passage; therefore the river had to be carried over half of the dam, which was first constructed some 4 ft above tailwater, until the other half of the dam was built. Gates 8 ft in height were needed to reduce the headwater elevation during floods. Because of the flood height the gates had to be lowered into the dam at high flood and, as the floods subsided, had to be raised to maintain maximum headwater. As the entire river section was needed for flood flow, the headworks, forebay, and power house had to be constructed on a side of the river involving the removal of about 120,000 cu yd of sandstone rock.

The modern development of the hydraulic turbine had only just begun at this time, and the choice was necessarily confined to the horizontal type, with six turbines on a common shaft being necessary to develop 2,700 hp, direct-connected to a generator of 1,670-kva capacity. To develop the maximum head of 20 ft, the turbine had to be set so low that at the time of floods the generators were below the level of the tailwater; and yet the upper turbine gates were so high that umbrella covering was necessary over the gates to prevent breaks in the vacuum. The generators were set in a watertight concrete pit, and the walls were extended well above flood-water level. These conditions required considerable ingenuity in design and were so well met that, in the thirty years which have elapsed since the plant began operation, few desirable changes have developed except the use of the more powerful turbines now available. This plant, costing about $2,500,000, has been successful both from an engineering and an economic standpoint.

In 1908, the Madison office under Mr. Seastone began plans for a hydroelectric plant at High Falls on the Peshtigo River in Wisconsin. This was a 6,000-kw plant under an 82-ft head and carried power to Green Bay, Wis., about 60 miles distant. It was a very different type of plant from the Kilbourn plant and, under the higher head, was constructed for about half of the unit cost of the low-head plant at Kilbourn.

In the summer of 1911 work was begun on a hydroelectric plant on the Wisconsin River just above Prairie du Sac. The river bed at this point is of sand, 100 ft or more in depth, and the entire structure, including both power house (350 ft long) and dam (about 1,000 ft long), was built on a pile foundation on this sand deposit. Excessive underflow was cut off by 50-ft steel sheeting above the power house and dam, and by 30-ft steel sheeting below these structures. Some erosion took place in the sand deposit downstream from the dam, and in 1935 the apron was extended about 55 ft, which added greatly to the safety and stability of the structure. The plant has been in use for twenty-seven years under heads of 37 to 38 ft and is apparently even more stable and safe than when first constructed.

These plants were followed by the design and construction of hydroelectric plants at Alpena, Mich., on Thunder Bay River; at Twin Falls on the Menominee River near Iron Mountain, Mich.; on the Brule River near Florence, Mich.; and on the Pine River in Wisconsin, southwest of Iron

Mountain (this was one of the earlier automatic plants and was operated from the main station at Twin Falls). Hydroelectric plants were also designed and constructed on the Peshtigo River at Johnson Falls, Caldron Falls, and Sandstone Rapids; and dams and plants were improved at Potato Rapids and at Peshtigo, Wis., on the same stream. Numerous other plants were also designed and constructed or revised and improved. A number of steam plants were built or rebuilt. An auxiliary steam plant was designed and constructed at Iron River, Mich., for the Peninsular Power Company. The steam plant of the Madison Gas and Electric Company was redesigned and reconstructed at Madison, first with a 5,000-kw unit and later with 10,000-kw and 15,000-kw units. The steam plant of the Mississippi Valley Public Service Company at Winona, Minn., was reconstructed and enlarged.

During Mr. Seastone's active period, water works plants were built, revised, or reconstructed at a number of places under his immediate supervision. Among these plants may be mentioned a new pumping station, water supply system, and storage reservoir systems at the original site in Madison. Operations had to be maintained while the new work was being done at the old site. A new artesian well and air-lift system, with new pumping plant and reservoir, were constructed at Rockford (Ill.). An electric pumping system was designed and constructed at Dubuque, Iowa, to replace a steam plant, and the water supply was also increased. A new pumping plant was designed and constructed at Decatur, Ill.; and a storage dam and improved filters were built for the Danville (Ill.) Water Company. A water works plant was designed and built at Prairie du Sac, and improvements were designed for Two Rivers, Wis.; Chisholm, Minn.; and West Allis, Wis.

Many reports were furnished on water power and water supply developments in various sections of the United States. One of the largest projects on which a report was rendered was the possible development of hydroelectric power on the Missouri River for the State of South Dakota at some five different localities within that state.

One of the most interesting, and perhaps most difficult, pieces of construction work designed and constructed under the general supervision of Mr. Seastone was a dam foundation on the Elwha River on the Olympic Peninsula in the State of Washington. This dam was a concrete structure built to create a 100-ft head in a narrow canyon on the river and was designed and constructed under an engineer who was evidently unfamiliar with hydraulic work. The dam had a pea gravel and sand foundation and was provided with an inadequate cutoff. When the head was raised and the plant was started, the river broke under the dam and washed out the foundation to rock at a depth of about 100 ft below the base of the concrete, leaving the dam suspended in the air. The plant had already cost 50% more than was warranted by the work done. The company was therefore almost exhausted financially, and the cost of diverting the river through the canyon walls, cofferdamming, and building a concrete foundation to the overhanging dam seemed to entail an expense perhaps equal to the expenditure already made.

Under these conditions such an expenditure was impossible. As an economic solution, it was decided to blast into the canyon and into the flowing river the rock cliffs on each side from a point about 350 ft below the dam up to the structure itself, after which the rock immediately above the dam was blown *en masse* into the stream to fill the gap and stop the stream flow. Before the placing of the rock fill was started, the stream had refilled with sand and gravel to a depth of about 50 ft. On this, immediately below the dam, a block of concrete weighing about 2,000 tons was built in a rectangle of steel sheeting to furnish stability to the rock fill. The space under the dam was filled, so far as practicable; and above the dam facines and mattresses of Douglas fir were used to catch and hold the fine material to make the rock fill above the dam watertight.

In the fall of 1913 some 40,000 cu yd of rock were blown into the stream just above the dam without injury to the structure. Although stoppage of flow was not immediately attained, this was soon accomplished by filling the depressions in the rock fill and by adding gravel and finer material. Although there is still a small flow through the gravel under this mass, the length of flow is so considerable that the velocity of seepage is reduced to such a degree that it leaves the toe of the rock fill without cutting velocity. This simple construction accomplished its object at a very low cost. The dam has been in use for twenty-eight years since its reconstruction, and the cost was less than one tenth of the estimated cost of a concrete substructure. Thus the financial life of the original company was saved and an otherwise useless plant was made serviceable.

Another interesting piece of work done under Mr. Seastone's supervision was the construction of a foundation under a completed power plant built on the soft bottom lands along Lake Michigan. This plant was designed and constructed by engineers not familiar with foundation work and was built on what is known as a "floating foundation." Unfortunately, one unit consisting of boilers and a 5,000-kw turbogenerator was first installed on one side of the building intended ultimately for two such units. Such a foundation always must be expected to settle somewhat, and for success such settlement must be anticipated and the foundation uniformly loaded. In this particular case, however, before the first installation was complete, the building settled unevenly, tipping toward the loaded side. The Madison office, under Mr. Seastone, was called in to underpin this completed building. The first substantial stratum that would carry the load was 40 ft below the ground level. After much study it was decided to support the structure by pairs of piles placed at about 25-ft intervals around the building. In each case the outer pile (40 ft long) was driven just outside the wall of the building to a firm foundation, while the twin pile inside of the building had to be sunk in 10-ft lengths joined together by steel sleeve joints. After these twin piles were driven, they were suitably capped and connected by heavy I-beams that supported a pair of lighter I-beams placed longitudinally in the wall of the building. After all the piles and I-beams had been placed, pairs of steel wedges were driven between the two sets of I-beams and concrete was placed around the beams. The settling stopped with the tightening of the wedges.

On February 17, 1930, the Madison Metropolitan Sewerage District was organized, and Mr. Seastone was one of the three original commissioners appointed by the County Court. The Madison Metropolitan Sewerage District, which included the City of Madison, four contiguous villages, and part of five adjacent townships, was formed to furnish sewerage services to a population in excess of 85,000. Mr. Seastone was elected President of the Board.

The work of the District was directly in the line of Mr. Seastone's study and experience. He was of great assistance in formulating and directing the policies of the District from the time of its organization. He thoroughly studied and gave close attention to every problem that arose. During his term of office the District expanded its interceptor system and greatly enlarged its sewage treatment facilities to make its treatment works one of the most efficient in the United States.

Mr. Seastone required practical solution of the problems of the District and was insistent that every dollar of public money spent under his direction return its full value in accomplishment. The people in the District, as is common in work performed for the public, cannot realize the debt they owe to the untiring interest and careful studies and supervision of Charles V. Seastone.

Considerable ingenuity is necessary to meet all of the contingencies of the diverse work in an engineering office, and it is seldom possible, with any degree of exactness, to place the credit for suggestions that bring success. If failures result, however, the responsibility is always with those in responsible charge. There is no doubt, however, that Mr. Seastone should be credited with his full share of the successful completion of the manifold problems and projects undertaken by his firm during the years of his connection with it. Honest and honorable in all of his thoughts and actions, and with high professional ability, he studied every project that came to his attention with an unbiased judgment and from every point of view. He was uniformly kind and considerate of his associates and assistants, and he utilized with the fullest possible credit all sound suggestions that came to him from any source.

On June 25, 1900, Mr. Seastone was married to Susan Sarah Bouton at Anna, Ill. Mrs. Seastone was the daughter of Harvey Cady Bouton, owner and publisher of the weekly, *Farmer and Fruitgrower*. Mr. Seastone is survived by his wife and two sons, John Bouton Seastone and Dr. Charles Victor Seastone, Jr.

He was a member of the Engineering Society of Wisconsin and the Technical Club of Madison. He was also a member for many years of the Madison Club and the Madison Rotary Club.

Mr. Seastone was elected an Associate Member of the American Society of Civil Engineers on December 5, 1906, and a Member on September 12, 1916.

VOLNEY RICHARD SEAWELL, M. Am. Soc. C. E.[1]

Died September 19, 1941

Volney Richard Seawell was born in Ukiah, Calif., on February 17, 1884, the son of John Henry and Lucy Frances (Watson) Seawell. John Henry

---

[1] Memoir prepared by De Witt L. Reaburn, M. Am. Soc. C. E.

Seawell was born in Lafayette County, Missouri, in 1847. He crossed the plains with his parents in 1853 and settled in Napa County, California. He was graduated from Pacific Methodist College, at Santa Rosa, Calif., studied law, and began practice in 1887. He was very successful. For many years he was a member of the California State Assembly and Senate. Lucy Frances Seawell was born in Sacramento, Calif., in 1852, and was a graduate of the first class of Mills College, at Oakland, Calif. Watsonville, Calif., was named for her family. Justice Emmet Seawell, a brother of John Henry Seawell, was a member of the California State Supreme Court for many years, and sat for some time as Chief Justice.

Volney Seawell's early education was acquired in the public schools of Ukiah. After high school, he educated himself by private study and extension courses in subjects pertaining to his work. In his school days, he was interested in athletics. He played football, held Pacific Coast records in the pole vault and high jumps, and was an enthusiastic "fan" for all sports.

The Seawell family were inclined to the law; but "Barney" (his nickname) was more interested in material things that were governed by the laws of nature. He evinced an early interest in electrical engineering, and began his long construction career in 1906, as electrician, with the Nevada Power and Mining Company, at Goldfield, Nev.

During the period 1907 to 1923, he successfully followed this field of work in the capacities of chief electrician, general foreman, and superintendent of construction on various projects in California, Montana, and British Columbia, Canada. His major assignment was with the Southern California Edison Company, at Big Creek, Calif., where he served, from 1921 through 1923, as superintendent of construction on that company's $19,000,000 hydroelectric project. In addition to the power houses, forebays, and penstocks, this project included 6 miles of 21-ft tunnel and a constant radius arch dam across the San Joaquin River, with tunnel intake, spillway, and gate-house structures.

In 1923 and 1924 he had charge of gravel testing and bridge foundation testing for the Exchequer Dam project of the Merced (Calif.) Irrigation District. Following this work, from 1924 to 1928, he was with the City of Los Angeles, Calif., as superintendent on the construction of the Mulholland Highway, Beverly Boulevard, and Cahuenga Pass projects, which involved heavy earth and rock excavation, paving, and structures.

In 1928 he was superintendent of construction for the H. W. Rohl Company, in Los Angeles, on additions to the Riverside (Calif.) Water System, which consisted of a reservoir and reinforced-concrete pipe lines. Following completion of this work, he was with the Alphonso E. Bell Corporation, at Bell Air, West Los Angeles, Calif., on research work for construction of a cement plant.

From 1929 to 1934 he was construction superintendent for the Macco Construction Company, of Clearwater, Calif., in charge of the branch office at Ellwood, Calif., 13 miles north of Santa Barbara, on steel piers, concrete foundations, etc., for marine oil wells (total cost, $2,000,000).

In 1934 Mr. Seawell became building inspector for the Los Angeles Board of Education, in charge of demolition of several large school buildings. He retained this position until 1935, when he became project engineer for the Work Projects Administration (WPA), at Los Angeles. He was soon made chief material inspector, and then zone engineer and manager of the Project Control Section.

In 1938 and 1939 he was with the Public Works Administration (PWA), at Los Angeles, as resident engineer inspector on school-building construction, but in the summer of 1939 returned to the WPA, at Los Angeles, as director, Division of Operations, in charge of all engineering, planning, and construction activities in Southern California, on which about 35,000 men were employed.

Director Seawell had an affable and agreeable disposition. He was kind and considerate and enjoyed the affection and respect of all who were associated with him. His cheery greetings and genial companionship will be missed by a host of friends and fellow engineers, who will continue to reflect, directly and indirectly, the ability, energy, and pioneering spirit of the man they knew and admired. The respect of his associates was evidenced by the large memorial wreath that was placed in the entrance of the WPA building in Los Angeles for a week following his death.

On February 1, 1911, he was married to his schoolmate, Ethel Elledge, who was his constant companion and partner through the years that followed. He is survived by his widow and his mother.

Mr. Seawell was elected a Member of the American Society of Civil Engineers on February 13, 1940.

ROBERT LOUIS SHAPE, M. Am. Soc. C. E.[1]

DIED JUNE 16, 1941

Bob Shape, as he was familiarly known to his many friends, was born in Milwaukee, Wis., on January 4, 1872, of German ancestry. His parents were Gustave Hermann Shape and Gertrude (Laubenheimer) Shape. He was the sixth of a family of nine children, and a good share of home duties and chores fell to his lot. In addition, however, he found time to study German, take swimming and violin lessons, and attend a gymnasium twice a week under a strict German instructor. At the age of twelve he played a violin solo in a concert hall where German families met on Sunday afternoons for beer, cakes, and coffee.

When he was thirteen his father took the family to Switzerland to live. There his study of the German language was continued and French was begun. He afterward became proficient in both languages. Because of the previous training in Milwaukee, he excelled in the gym work there and developed a fine physique, attaining his six-foot height at an early age. Mountain climbing and expeditions on foot to near-by points of interest, in which the entire family joined, afforded an instructive and enjoyable pastime as well as a physical benefit.

---

[1] Memoir prepared by Isaac Harby, M. Am. Soc. C. E.

In 1887, it was decided that Bob would study architecture, and his father entered him in the University of Winterthur in Canton of Zurich, Switzerland; but fate ruled otherwise, for soon after this the father died and the family moved back to Milwaukee. Here he re-entered the public school where he was definitely handicapped through a deficiency in English grammar. This handicap was made up the following year, however, so that he was able to enter the only high school in Milwaukee at that time. He enrolled in the three-year science course. He also continued his musical education in the Milwaukee Conservatory of Music, played in the orchestra of the Congregational Church, and at seventeen became the leader at a salary of $5 per week. Summers were now being spent on the farm of an uncle where the harvest season afforded beneficial physical exercise from sunup to sundown.

Having graduated from high school with honors, the second highest in his class, and from the Conservatory of Music with a gold medal for progress and proficiency, he entered Cornell University, at Ithaca, N. Y., in the fall of 1891 for the course in architecture. He joined the Beta Theta Pi fraternity, was elected to the Aleph Samach Society and to Sphinx Head, and at graduation to Zeta Epsilon.

His six-foot athletic body envisioned an oarsman, so he tried out for the crew and made it in his freshman year. He rowed in the varsity through his sophomore, junior, and senior years under the coaching of the famous Charles Edward Courtney. In his senior year he captained the crew and went with it to England when it rowed at Henley-on-Thames. His last-used oar is still a cherished trophy at Cornell.

Mr. Shape's professional career began in New York, N. Y. After graduation from Cornell in 1895 with first honors, he went to work as a draftsman in the office of the important architectural firm of George B. Post and Son. Through his continued interest in rowing he joined the Atlanta Boat Club and participated in some races in which it was a contestant.

When the war with Spain began in 1898, Mr. Shape enlisted with the 8th U. S. Infantry for a period not to exceed three years and was in active service in Cuba. One day, while he was at headquarters near Sabony, there suddenly was heard a heavy cannonading and all hands rushed to a point of vantage. Here was witnessed the naval battle of Santiago de Cuba, and those at headquarters on that day were the only persons in the army to see that victory. Private Shape's enlistment lasted thirteen months—five in active service and eight off duty on the sick list.

After traveling in the West for three months to recuperate, he returned to his old job in New York City. His duties now consisted of structural steel designing and superintending the construction of the new Stock Exchange and the College of the City of New York. Other engagements followed, including designing with Clinton and Russell, architects, and with the Cleveland (Ohio) Electric Illuminating Company.

In 1905 the architectural firm of Shape and Bready (afterward Shape, Bready and Peterkin) began to function. Its work included the design of the following buildings: (1) The Candler Building on West 42d Street; (2) a number of Edison phonograph shops; (3) a cooperative apartment at 50 West 67th Street; and (4) a cooperative garage on 67th Street, the first to obtain a permit under the New York City Zoning Law.

From 1918 to 1926 Mr. Shape was associated in the work of the following organizations:

(*a*) Todd Drydock and Shipbuilding Corporation, Tacoma, Wash.—production manager.

(*b*) J. J. Coughlan Shipbuilding Company, Vancouver, B. C., Canada—works manager.

(*c*) William J. Taylor Company, contractors, New York City—in charge of construction of Canadian Pacific Building.

(*d*) Starrett and Van Vleck, architects, New York City—in charge of construction of Equitable Life Assurance Society Building.

(*e*) Clinton and Russell, architects, New York City—designing.

(*f*) Charles M. Hart, architect, New York City—engineer and construction superintendent.

Mr. Shape subsequently became a member of the firm of Hart and Shape, which has to its credit some apartment houses, schools, hotels, an armory in Brooklyn, N. Y., and a hospital in Rockville Center, Long Island, N. Y. The last five years of his life were spent in the service of the federal government.

In 1935 the Resettlement Administration began its activities in the construction of suburban projects popularly known as "Greenbelt Towns." Mr. Shape was appointed principal architect in connection with the planning of some five hundred single-family homes at Greenhills near Cincinnati, Ohio. After this work was completed, he became senior engineer for the Public Works Administration with work on housing projects at various locations throughout the United States.

In December, 1940, he received an appointment from the Public Buildings Administration as senior construction engineer with instructions to report for duty on December 12, but on that day he was not well and requested a postponement of the duty date. He entered the Veterans' Hospital in New York City for examination and treatment, and it was found that he was suffering from an insidious disease for which there was no known cure. After a few months, death overtook the career of one who had achieved excellence in his chosen field and who had served his country well.

Throughout his life he maintained an interest in music, and, being well trained, was a skilful violinist. His unassuming attitude and genial manner to all engendered lasting friendships. In addition to membership in the Society, he was a member of the Architectural League, the Cornell Club, and the New York Athletic Club. His home was at Ridgefield, Conn.

He is survived by his wife, the former Elizabeth Powell, to whom he was married on July 24, 1911. A son, Norman Lee Shape; a daughter, Elizabeth

G. (Mrs. Denis Mulligan); and two stepdaughters, Margaret Stoddart (Mrs. Theodore Cuyler Speers) and Marion Stoddart (Mrs. Harry P. Warren), also survive him.

Mr. Shape was elected a Member of the American Society of Civil Engineers on November 14, 1927.

HENRY GARNETT SHIRLEY, M. Am. Soc. C. E.[1]

Died July 16, 1941

Henry Garnett Shirley was born at "Locust Grove," Summit Point, W. Va., on October 28, 1874, the son of Robert Vinson and Julia (Baylor) Shirley. He received his preparatory education in the public schools of Jefferson County, West Virginia, and at the Charles Town (W. Va.) Male Academy. He entered the Virginia Military Institute at Lexington, Va., in the fall of 1892 and was graduated from the engineering course in 1896. He was prominent in many phases of barracks life at Virginia Military Institute, a member of the football team, and first lieutenant of Company "A," corps of cadets. Upon graduation he accepted the position as Commandant and Professor of Military Science at Horner Military School, in Oxford, N. C.

At the outbreak of the war with Spain in 1898, Mr. Shirley enlisted and served with the U. S. Volunteers. At the close of that war he began his engineering work on the New York Central and Hudson River Railroad. Later he worked for the West Virginia Central and the Baltimore and Ohio railroad companies; for a time he also was connected with the engineering department of the District of Columbia. After five years of experience in engineering—which were required for a degree from the Virginia Military Institute—he was awarded the degree of Civil Engineer by that institute.

While working for the Baltimore and Ohio Railroad Company, Mr. Shirley was with the corps of engineers that retraced the location of the South Pennsylvania Railroad, which was then being surveyed by the Baltimore and Ohio Railroad Company for a possible low grade line over the Allegheny Mountains. This location is now a part of the recently completed superhighway from Carlisle to Pittsburgh, Pa.

Mr. Shirley's principal engineering work was in the development of modern highways. He first began highway work as roads engineer in Baltimore County, Maryland, in April, 1904, following which he was appointed to the office of chief engineer of the Maryland State Roads Commission. While in this position Mr. Shirley was one of the organizers of the American Association of State Highway Officials in 1914 and was the first president of that organization. He served as president of the Association for two years, having been the only president to serve for that length of time. At the time of his retirement as president he was presented with a large silver cup by his associates. He continued as a member of the Executive Committee of the Association and was a member of the Special Committee on Highway Transport that cooperated with the National Automobile Chamber of Commerce. In 1918 Mr. Shirley was made executive secretary of the Federal Highway Council, a body which advised the federal and state governments and colleges and universities in the matter of highway research conducted by various agencies. It also gave advice as to the problems that should be investigated.

---

[1] Memoir prepared by W. R. Glidden and E. M. Hastings, Members, Am. Soc. C. E.

At the outbreak of the first World War Mr. Shirley was made a member of the Highway Transport Committee, Council of National Defense, and gave his untiring energy to the end that the roads of the United States might be in shape so that necessary materials and munitions of war could be trucked over them to the camps and ports.

In 1920 Mr. Shirley was again made engineer of Baltimore County. At this time the suburbs of the City of Baltimore were undertaking a huge program of street and road building and the construction of various public utilities. He remained in this office until 1922 when he was called to Virginia to be the chairman of the State Highway Commission. From that date until his death Mr. Shirley headed the Virginia State Department of Highways, first as chairman of the Highway Commission and later as commissioner, Department of Highways. He served under five governors, and his work in this department is known throughout the United States. Under his administration the highway system was expanded so that today the State of Virginia occupies a most enviable position in modern highway development.

In 1925 Mr. Shirley was elected to the Executive Committee of the American Road Builders Association and the following year was elected president of that Association. As president he appointed delegates to the International Road Congress at Milan, Italy, and was himself subsequently appointed as a delegate to various International Road Congresses by federal authority.

Mr. Shirley was awarded the honorary degree of Doctor of Science by the University of Maryland, in Baltimore, and a similar honorary degree by Hampden-Sydney College, in Hampden-Sydney, Va. He was one of the organizers of the Virginia Section of the Society and served a term as president of the Section. He was always deeply interested in the welfare of engineers and the furtherance of the engineering profession. He maintained a loyal and active contact with his alma mater, the Virginia Military Institute, was constantly concerned as to its welfare, and assisted in progressive efforts to further its interests. He was a man of rare intellect and had a peculiar personal charm that gave him great ability as an executive; this, coupled with the skill of a master of engineering, made him an international figure in the highway world. These same traits placed him, in the minds of his friends and close associates, in a position even higher than that of his national reputation, so that it would be difficult to find a department more completely coordinated and cooperative than the Virginia State Department of Highways. Mr. Shirley possessed a disarming frankness in his approach and discussions with men that brought out the best in all those with whom he came in contact; he was frank and open in his dealings and handled many difficult situations in his administration of the Virginia State Department of Highways so successfully that he was looked upon as one of the outstanding officers of the state government.

On November 29, 1904, Mr. Shirley was married to Alice Robertson Graham, of Oxford. She died on October 22, 1916. There were five children by this marriage, Robert Vinson, Lucy Graham (Mrs. Leon Otis), Augustus Graham, Julia Baylor (Mrs. Fred Patterson), and Alice Graham, all of whom survive him. On September 17, 1930, he was married to Sara Anne Berkeley of Richmond, Va., who survives him. He is also survived by a brother, George; three sisters, Mary, Ruth, and Julia; and a grandson, Henry G. Shirley 2d.

Mr. Shirley was elected a Member of the American Society of Civil Engineers on June 30, 1911.

BURR HENRY SIMPSON, M. Am. Soc. C. E.[1]

DIED AUGUST 10, 1941

Burr Henry Simpson was born on January 6, 1885, at Buckhannon (Upshur County), W. Va., the son of Allen A. and Elizabeth (Lorentz) Simpson. He had one sister who preceded Mr. Simpson in death. He was a descendant of the Burr family, of whom Aaron Burr is the best known.

Mr. Simpson was educated in the public schools at Buckhannon, and continued his studies with a scientific course at West Virginia Wesleyan College, in Buckhannon. Later he studied civil engineering at Ohio State University, in Columbus, Ohio. His collegiate training extended from 1900 to 1903.

He began his practical experience in engineering work in September, 1904, as a chainman, rodman, and instrumentman with the Coal and Coke Railway Company in West Virginia, where he remained until July, 1905. From April, 1906, to October, 1907, he served as instrumentman with the Chesapeake and Ohio Railway Company on double-track construction between Richmond and Newport News, Va.; as instrumentman and chief of party on the Lewiston and Southeastern Electric Railway, in Idaho; as chief of survey party for the Inland Power and Electric Company, in the State of Washington, on reconnaissance, preliminary, and partial location (53 miles); and as assistant engineer for the Oregon Railroad and Navigation Company in the states of Washington and Oregon on branch-line construction, drainage, tunnels, and stations.

From October, 1907, to November, 1909, he was engaged in private practice at Spokane, Wash., on location, design, and construction of a 9-mile mountain railroad spur; surveys for water-power development and irrigation projects; underground and surface work for copper mining companies; and as United States Deputy Mineral Surveyor.

In April, 1911, Mr. Simpson became a draftsman and computer with the Frog and Switch Department of the Pennsylvania Steel Company, at Steelton, Pa., on special track work, and then with the Track Department of The Falk Company, in Milwaukee, Wis. From July, 1912, to January, 1913, he was a civil engineer for the Gogebic and Iron Counties Railway and Light Company, in Ironwood, Mich., on location and construction of 7 miles of electric railway, including a filtration plant. Following this work he was a computer and assistant engineer for the J. G. White Company, in New York, N. Y., on an appraisal survey of the Atlantic Coast Line Railroad from September, 1913, to May, 1914.

---

[1] Memoir prepared by Howard A. Levering, M. Am. Soc. C. E.

Mr. Simpson entered the highway engineering field in May, 1914, with the Ohio State Highway Department, in Columbus. He was acting resident engineer on construction of the national road between Hendrysburg and New Concord, Ohio, and spent one year as deputy engineer in Knox County, in charge of surveys and construction for the State Highway Department of Ohio. Between April, 1917, and August, 1918, he was field engineer, and from March, 1919, to January, 1921, he was field engineer and assistant district engineer for the Portland Cement Association, in Pittsburgh, Pa., on promotion work on concrete roads.

During the period from August, 1918, to March, 1919, he was with the U. S. Ordnance Department, in Cleveland, Ohio, first as production assistant, visiting shell plants (until November, 1918), and then as special assistant to the Claims Board, being referee in the settlement of claims.

Mr. Simpson was sales engineer for the Kentucky Rock Asphalt Company, in Louisville, Ky., from January, 1921, to November, 1926. He was city engineer for his home city of Buckhannon from November, 1926, to January, 1929, in charge of design and construction of streets, sewers, etc. Mr. Simpson supervised the construction of the Pittsburgh-Butler (Pa.) Airport in 1929.

From 1930 to August, 1933, Mr. Simpson served again as city engineer of Buckhannon. He then became district engineer of the fifth district, at Keyser, W. Va., for the State Road Commission. Later he was made project engineer for the Commission with headquarters at Charleston, W. Va., in which position he served until he was appointed state road commissioner by Governor H. G. Kump in August, 1935. He was reappointed to the same office by Governor Homer A. Holt in March, 1937, and served in this capacity until his resignation in March, 1941.

Following his resignation as state road commissioner, Mr. Simpson accepted the position of president and general manager for the West Virginia Sand and Gravel Company, and of the Standard Brick and Supply Company, both of Charleston. These positions he held until about three weeks prior to his death, when he resigned from them because of ill health.

Mr. Simpson was a Mason and belonged to the Shrine. He was a member of the West Virginia Society of Professional Engineers, and was a former chairman of the State Aeronautics Board. He also was a former member of the State Publicity Commission.

His varied and far-flung experience in the field of engineering gave him a bright outlook on life and a broad vision as to the value of engineering principles and accomplishments in behalf of the public and humanity. Good engineering was paramount in his code of life.

He was a highly efficient and indefatigable public servant. His striking personality and genuine sincerity won for him a legion of friends. He placed the public welfare ahead of his own aggrandizement. His retiring disposition and humble modesty were true tests of his real ability and untrammeled honesty. Mr. Simpson would make no promises unless he knew that they could be fulfilled, which is an admirable and outstanding tribute to any man. His love for his fellow men and his devotion to his friends were ever manifest in his firm and enthusiastic handclasp.

The career of Mr. Simpson, which came to an abrupt close at the end of more than fifty-six years, was climaxed by his service to the people of his native State of West Virginia as its state road commissioner. The greatest monument that could be erected to his memory, aside from the sterling quality of his character and friendship, was the great advancement that was made in improved highways of West Virginia during his tenure of office. His time, thought, and energy were completely devoted to a well-rounded highway system. Better roads throughout the entire state for all of the people was his dream and almost his realization. The vast network of farm-to-market roads was planned and consummated during his commissionership, and was a rare tribute to Burr Henry Simpson, the man, engineer, and friend.

He died on August 10, 1941, and interment was at the Heavener Cemetery in Buckhannon on August 12. He is survived by his mother.

Mr. Simpson was elected an Associate Member of the American Society of Civil Engineers on December 6, 1915, and a Member on October 1, 1928.

CHARLES HENRY SMITH, M. Am. Soc. C. E.[1]

Died December 20, 1940

Charles Henry Smith was born at Winthrop, Mass., on June 29, 1868, the son of Alexander and Mary Ann (Mears) Smith.

He began his engineering work in 1890 as rodman with the Metropolitan Sewerage Commission, at Boston, Mass., and continued with that organization through the grades of instrumentman, inspector, draftsman, and foreman of construction until 1896. His next engagement was with the Boston Transit Commission, first as inspector on contract work, then as engineer in charge of construction (night) on two sections of open-cut, heavy brick and concrete masonry; tunneling; street paving; and relaying sewer, gas, and water pipes. In 1898 he built a dredge and superintended dredging in Back Bay Fens for Perkins, White and Company, in Boston.

Mr. Smith went to Honolulu, Territory of Hawaii, in 1898, where he served as designing engineer for the Department of Public Works for more than eight years, designing and constructing reservoirs, sewers, etc. For nearly a year he was engineer and general superintendent with E. J. Lord, general contractor, in Honolulu.

---

[1] Memoir prepared by O. E. Stanley, M. Am. Soc. C. E.

Returning to "The States" in 1908, Mr. Smith spent the next two years in private practice in Seattle, Wash., and Portland, Ore. In 1910 he began his long service in the Bureau of Sewers, City of Portland, which lasted until his death, with the exception of about five years. During these five years he was associated with Barr and Cunningham, Consulting Engineers, in Portland, as project engineer on the Malheur Drainage District; as resident engineer on other work outside of Portland; and with the Warm Springs Irrigation District at Vale, Ore., for nearly a year, as construction engineer on the Warm Springs Dam.

In his work for the City of Portland, Mr. Smith began as chief inspector of sewer construction, and then was promoted to sewer engineer in charge of sewer design and construction. Among his more important studies were preliminary plans and estimates for the Park Rose and Altamead District and for the Portland Sewage Disposal System. The latter included the necessary intercepting sewers. This was the work upon which he was engaged at the time of his final illness.

In his early manhood, Mr. Smith was interested in building and sailing small yachts and continued to enjoy this sport while living in Honolulu. He later derived pleasure from collecting and refinishing antique furniture, but during his later years his whole interest appeared to be occupied by his profession.

Mr. Smith was a registered professional engineer in Oregon and was a life member of the Professional Engineers of Oregon. He was a member of the Order of the Mystic Shrine, first as a member of Aleppo Temple in Boston, and later as one of the sixteen charter members of Aloha Temple in Honolulu.

On June 7, 1900, he was married to Margaret McCorriston in Honolulu. Mrs. Smith and two daughters, Theresa (Mrs. Gail Miller), and Frances E. (Mrs. Hollister M. Stolte), survive him. He is also survived by three brothers, Chester, Percy, and Lewis.

Mr. Smith was elected a Member of the American Society of Civil Engineers on August 17, 1936.

CARLETON WILLIAM STURTEVANT, M. Am. Soc. C. E.[1]

Died September 16, 1941

From pioneer home in Missouri to construction on the Panama Canal in one's own lifetime seldom falls to the lot of an engineer—that is what makes the life of Carleton William Sturtevant stand out. Advance from assistant on a Mississippi River Survey party to Colonel of the 15th Engineers, Civilian Member of the Mississippi River Flood Control Board, and Consulting Engineer of the Fort Peck Dam, show the advance that can be made by an engineer in the U. S. Government service.

---

[1] Memoir prepared by L. F. Bellinger, M. Am. Soc. C. E.

Aside from government work, Mr. Sturtevant spent one year in railroad work as transitman and resident engineer. For 7½ years (1902 to 1909), he was in dredge work for the Atlantic Gulf and Pacific Company at Vicksburg, Miss., Mobile, Ala., Tampa, Fla., and Fort Ann, N. Y., made examinations of Cape Cod Canal, and the harbor of Lynn, Mass. He built the first two dredges for the Panama Canal Commission.

He was with the James Stewart Company for four years and built 93 miles of New York State Barge Canal from Montezuma Swamp to Oneida Lake and Fulton. For three years he was with the New York State Dredging Company as general superintendent on six barge canal contracts, and on a 5,000,000-cu-yd fill at Utica, N. Y., for the New York Central Railroad Company.

After six months with James Stewart again, on Hudson River work, he was ordered to active duty as Major, Engineers Reserve Corps. From May 25, 1917, to July 6 of that year, he was Major of the 15th Engineers under the then Colonel Edgar Jadwin,[2] M. Am. Soc. C. E., under whom he had served in Cuba as a Captain in the 3d U. S. Volunteer Engineers. He was made Lieutenant Colonel on July 6, and sailed on the *Baltic* for Liverpool, England, on July 9, arriving there on July 19. The Regiment's 32 cars of railroad tools filled 100 English cars, and all were transferred from Southampton to Le Havre and to Vierzon. Only the 16th Infantry and the 18th Infantry of the regular Army preceded them to France, having gone directly there. The English said they were the first armed regiment of foreign troops to be in England since William the Conqueror arrived from France, in September, 1066, nearly 851 years before. The Normans defeated the English on October 14, 1066, at the Battle of Hastings.

The work in France included selecting and building a harbor, a railroad, and storage yard at Gievres. He moved headquarters from Vierzon to Liffol-le-Grand, and to Solmary yard. He helped build the railroad from Verdun to Conflans that was destroyed by the Germans just before the Armistice, and took the first trainload of food in 3½ years into Sedan.

Colonel Jadwin was promoted December 17, 1917, to Brigadier General and the work mentioned previously was nearly all done under the command of Lieutenant Colonel Sturtevant, who was commissioned Colonel on November 13, 1918, two days after the Armistice.

His regiment moved to Bordeaux, France, on January 21, 1919, and then to Poullic to await a ship to the United States. On April 13, the regiment sailed on the *Santa Clara,* arrived in New York, N. Y., on April 27, 1919, and was mustered out after two years of service.

Colonel Sturtevant was the civilian member of the Jadwin Board of three, for Mississippi River Flood Control. Duties on this Board occupied his time from May 16, 1928, to January 12, 1929, on which date the Board's work was completed.

A Citation signed by Gen. John J. Pershing was awarded to Colonel Sturtevant on April 19, 1919, "For exceptionally meritorious and conspicuous services at Gievres, France." In addition, on June 7, 1919, General Pershing wrote him a personal letter commending him as follows: "Your services both as Lieutenant Colonel and Colonel of the 15th Engineers on the important construction projects at Gievres and at Liffol-le-Grand have been of the highest character."

---

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 96 (1932), p. 1498.

The U. S. Engineers ordered Mr. Sturtevant in 1891 to build a small scale detail of a "caving bank revetment mattress" which was sent to the World's Fair in Paris, France. In 1900 the French Republic awarded him a diploma and a silver medal for this model. The medal was awarded in silver. It was delivered in bronze, because of lack of funds.

On the more personal side of Carleton William Sturtevant's record we have:

Carleton William Sturtevant was born on January 25, 1864, in Ruggles Township, Ashland County, Ohio, and died at Atlanta, Ga. He had four sisters. He was the son of Samuel Carter Sturtevant of Ashland County, Ohio. (On his father's side, seven ancestors came to the United States on the *Mayflower*. The name is of Norman-French origin.) His mother was the former Adelaide Elizabeth Taylor of Cedarville, N. Y. (She was a fourth cousin of her husband; hence they had about the same ancestry—Norman French.) With such a heritage, is it any wonder that Colonel Sturtevant had so distinguished a career?

He was married three times—first, on May 10, 1887, to Mary Jane Atcheson, who died on May 16, 1892. His second wife was Eva May Peterson, to whom he was married on February 16, 1893. She died on July 31, 1899. She bore him his two children. On September 3, 1902, he was married to Rosalie Lightcap Denio, who survives him.

As an interesting personal note, attention is invited to what may be called the family domiciles of three Life Members of the Society. Mention was made of Cedarville (about eight miles south of Mohawk, N. Y.) as being the home of the mother of the Colonel of the 15th Engineers. The Colonel of the 17th Engineers, William Greene Atwood, M. Am. Soc. C. E., had a family domicile at Middleville, N. Y. (about eight miles north of Mohawk). A Captain of the 3d U. S. Volunteer Engineers was born in Mohawk (the writer of this memoir).

On certain occasions much too widely separated, these three dined together and thoroughly enjoyed reminiscences of Mexico, Alaska, Cuba, Europe, and the Orient. Speaking for myself, there prevailed a warmth of feeling, a lasting friendship, and an eager anticipation of joy at the hope of an early repetition of the reunion of these three.

Colonel Sturtevant's father left a diary covering the period from July 4, 1859, to July 5, 1869, which abounds in wonderfully sound patriotic paragraphs of a political and economic nature. It is given in full in the Colonel's family genealogy, from which the foregoing personal data are taken.

The Colonel was a graduate of the University of Missouri, at Columbia, in the Class of 1884. In 1929 his Alma Mater conferred on him the honorary degree of Doctor of Laws.

At the time admission to the Society was through election by the membership, and a certain number of adverse votes precluded admission, he was elected a Member on October 2, 1901. He was thereby senior to the writer of this memoir, who was elected a Member on November 6, 1901. Some good engineers were repeatedly blackballed by contractors' friends who were already in the Society.

Captain Sturtevant's services in the Spanish American War with the 3d U. S. Volunteer Engineers deserve a separate paragraph. The data are taken from the history of the regiment written by Maj. John L. Van Ornum, M. Am. Soc. C. E. Our Col. D. D. Gaillard was a "regular" Captain in the Corps of Engineers. One of our Majors, Edgar Jadwin, was a "regular" First Lieutenant, Corps of Engineers. When he was retired, he became Lieutenant General.

The law creating the Volunteer Engineers regiments was the Act of May 11, 1898. Colonel Gaillard accepted his commission on June 16; most of the regimental officers were commissioned on July 13. The first company was mustered in, July 25, two thirds of the companies by August 4, and the last company on August 20. From St. Louis, Mo., the regiment moved to Lexington, Ky., on September 20; then to Macon, Ga., on November 13. A mutinous colored regiment, the 6th Virginia, was placed "in arrest" by the regiment on November 19. We were reviewed by President McKinley on December 19. Our 3d Battalion with Captain Sturtevant was in Matanzas, Cuba, on December 23, and raised the American Flag there, on January 1, 1899, when the Spanish flag was hauled down. The headquarters Battalion reached Cienfuegos, Cuba, on February 10, 1899, "received" General Gomez and his "army" of about fifty, on February 13, and "received" our Secretary of War, Russell A. Alger, on March 30, in Cienfuegos.

Captain Sturtevant was commanding Officer of the 3d Battalion in Matanzas, from March 1 to March 15, 1899. In this period he had occasion to discipline an enlisted man, so he "preferred charges" as a company commander, tried the charges as Summary Court Officer, then executed the sentence as Battalion Commander. This is some kind of a record, I believe.

The second Battalion sailed from Cienfuegos on April 13; 1st and 3d Battalions sailed from Havana, Cuba, on April 15; all left Savannah, Ga., on April 23, and all were mustered out on May 17, 1899, at Atlanta. Every year in various parts of the United States the surviving members of the "Old Third" have celebrated the May 17th muster-out of the regiment. What other regiment can boast that it has never missed a single anniversary meeting in forty-two years?

The national organization known as "Third U. S. Volunteer Engineers" (War with Spain) has kept alive the sentiments, the friendships, and the patriotic loyalties of its members through all these years. The National President for 1941 was Carleton William Sturtevant; he died in harness. His last duty on the Board of Consulting Engineers for Fort Peck Dam was in July, 1941, when he was seventy-seven and one-half years old.

Colonel Sturtevant was six feet tall. He was strong in mind, strong in body, strong in character. He was indeed a man!

A brief outline of his work is given in *Who's Who in Engineering,* page 1274, 1931 edition. His application for membership in the American Society of Civil Engineers in 1901 is in the files of that Society. Details of his professional engagements are in his "Professional Record" received by the Society on April 16, 1941.

Colonel Sturtevant was elected a Member of the American Society of Civil Engineers on October 2, 1901. He became a Life Member in 1935.

FRANK STONE TAINTER, M. Am. Soc. C. E.[1]

DIED SEPTEMBER 25, 1941

Frank Stone Tainter, son of Thomas Phillips and Josephine (Brooks) Tainter, was born on December 16, 1862, at Morristown, N. J. He was educated at Morris Academy, in Morristown, and took special engineering courses at Princeton University, in Princeton, N. J.

In 1883, before reaching the age of twenty-one, Frank S. Tainter began his engineering career by joining the staff of the Delaware, Lackawanna and Western Railroad Company on location and maintenance work. Railroad construction was at its peak at that time, and in the following decade Mr. Tainter did work on many other lines, including the Delaware and Hudson, Boston and Maine, Southern, and the Texas and Pacific railroads. Between 1888 and 1891 he was in the employ of the Metropolitan Telephone and Telegraph Company as construction engineer and superintendent of pay stations. In the course of these engagements he gained considerable experience not only in accurate surveying, but also in the design and construction of heavy masonry work (such as retaining walls, bridge foundations, and building constructions) and of water supply, water treatment, and sewage disposal plants. This experience he put to excellent use in later years.

In 1896, Mr. Tainter established his own consulting engineering office at Bernardsville, N. J., which he maintained for the forty-five years preceding his death. During this period, between 1902 and 1910, he was a member of the engineering firm of E. A. Stevens and Company, with offices at Hoboken, N. J.; and, between 1920 and 1941, he also maintained an office in New York, N. Y., as an associate of Parsons, Klapp, Brinckerhoff and Douglas, Consulting Engineers.

In 1917, when the United States entered the first World War, Mr. Tainter applied for a commission in the service and was appointed by President Woodrow Wilson as a Major in the Corps of Engineers, U. S. Army; he retired with the rank of Lieutenant-Colonel in 1920. During his service he designed and was in charge of construction of the Aberdeen Proving Ground in Maryland.

In the course of his engineering practice, which extended over more than half a century, Colonel Tainter designed and supervised the construction of a large number of engineering works. He was chiefly active in surveying, water supply and sewage disposal projects, bridges, and private and public property developments. Only a few of his many works in these several lines will be mentioned.

---

[1] Memoir prepared by Eugene E. Halmos, M. Am. Soc. C. E.

Surveys.—Map of 130,000-acre game preserve in Beaufort and Hampton counties, South Carolina; map of Oyster Bay Township, Long Island, N. Y.; and map of Southampton, Long Island, N. Y.

Water Supplies.—Pottersville, N. J.; Castleton on Hudson, N. Y.; Kingsport, Tenn.; Appalachia, Va.; and Norwood, Ohio.

Most of the water supply projects included dams of various types and heights, some of which reached national recognition, such as the Carnegie Dam at Princeton and the dam at Kingsport.

Sewage Systems.—Aberdeen Proving Ground; Clearwater, Fla.; Kingsport, Tenn.; and Collingswood, N. J.

Bridges.—Carnegie Bridge at Washington Crossing, Princeton; highway bridge, Peapack, N. J.; causeway at Blairsden, Peapack; and railroad bridge, Dansville, N. Y.

Property Developments.—Estate of C. Ledyard Blair, Peapack; estate of Marshall Field, Lloyds Neck, Long Island, N. Y.; Peachtree Heights Park, Atlanta, Ga.; and Somerset Hills Country Club, New Jersey.

Colonel Tainter was one of the last of the generation of engineers, affectionately termed "old-timers," whose status in the profession paralleled that of the family physician. The first part of his career came in a period when the profession was not crowded as it is now, and when the engineer with general practice could not afford to specialize. He splendidly fulfilled the duties of a general practitioner.

Colonel Tainter, although a man of slight build, had tremendous energy, was uncommonly active, and was a tireless worker. He personally conducted all work that he undertook, delegating only details to subordinates. Although this method of managing his affairs kept him extremely busy, he was always willing to devote his time and money in the interest of the community. Thus, in 1911, on the request of the then Governor Woodrow Wilson of New Jersey, he went to England to obtain firsthand information on methods of construction, surfacing, and maintenance of British roads. His report was published in the *Year Book* of the State of New Jersey in 1912. For periods of one to four years he held the following positions: Acting chief consulting engineer and acting engineer of the Highway Department of the State of New Jersey; acting county engineer for Morris and Somerset counties, New Jersey; engineer commissioner and acting chairman of New Jersey State Board of Health; engineer member and vice-chairman of Tri-State Commission for the abatement of contamination of waters surrounding the New York metropolitan area; and consulting engineer for the Roosevelt Memorial Association.

In addition to his professional work, Colonel Tainter took great interest in the social life of his community. He was well known, liked, and respected in the entire State of New Jersey and particularly among his neighbors at Far Hills, where he had a beautiful home, built and developed by himself, and of which he was justly proud. His hobby was horseback riding and he participated in fox hunting until a few years before his death.

In 1892, Colonel Tainter was married to Susan Bayard, who survives him.

He was a member of the following organizations: American Institute of Mining and Metallurgical Engineers, American Association for the Advancement of Science, Society of American Military Engineers, American Water Works Association, Institution of Civil Engineers, London, Royal Society of Arts, and Sons of the American Revolution. He was also a member of the Engineers' Club, Down Town Association, Morristown Club, and Essex Fox Hounds.

Colonel Tainter was elected an Associate Member of the American Society of Civil Engineers on January 3, 1900, and a Member on March 31, 1908. He became a life Member in 1933.

BENJAMIN FRANKLIN TAYLOR, M. Am. Soc. C. E.[1]

Died April 18, 1942

Benjamin Franklin Taylor was born at Proctor, Vt., on November 9, 1881, the son of Benjamin Franklin Taylor and Jessie (Smith) Taylor. His preliminary education was obtained in the grade school and high school at Proctor, and he was graduated from the University of Vermont, at Burlington, with the degree of Bachelor of Science in Civil Engineering in 1907.

Immediately after graduation, Mr. Taylor accepted a position as rodman with the New York, Ontario and Western Railway Company. In 1908 he became a rodman with the New York State Highway Department where he was employed until 1917. In the latter year, he entered the employ of the Construction Division of the War Department, Quartermaster Corps, at Washington, D. C., as highway engineer.

On April 4, 1919, Mr. Taylor was employed by the Public Roads Administration as highway engineer at Washington, D. C. Shortly after his entrance into the service, he was transferred to Division 5 with headquarters at Omaha, Nebr. He was promoted to senior highway engineer in 1928, which position he held until his death.

During 1939 Mr. Taylor took a leave of absence for a year due to nervous prostration. When he returned to duty, he appeared to be in good health. He had been residing at an apartment hotel in Kansas City, Mo., and on or about April 3 he was awakened by flames and smoke in his room. He undoubtedly received a severe shock. He was taken to the Crestview Sanitarium, in Kansas City, where he died on April 18, 1942, at 9:30 p.m. His body was taken to Proctor for interment.

He leaves a wife, Mrs. Reland S. Taylor, to whom he was married on June 3, 1935; a son by a former marriage, Brooks S. Taylor; a sister, Mildred E. Taylor; and two brothers, C. M. Taylor and Richard H. Taylor.

Mr. Taylor was elected a Member of the American Society of Civil Engineers on March 10, 1930.

---

[1] Memoir prepared by E. L. Brown, M. Am. Soc. C. E.

ROBERT ANDREW THOMPSON, M. Am. Soc. C. E.[1]

DIED MAY 30, 1941

Robert Andrew Thompson was born at New Waverly, Walker County, Tex., on July 11, 1869, the son of Col. Andrew Jackson and Mary (Gillespie) Thompson. The family lost its holdings after the War Between the States and, although Colonel Thompson's negroes settled around him and worked for him, he was too old to make a new start. Before he was twelve years old, young Thompson was managing his father's plantation and marketing such products as honey, and especially prepared mutton, for which products the plantation had been noted.

Mr. Thompson's early education was obtained by night study under his mother's direction, after days spent in fields and in stock feeding and breeding. He read every book he could secure within horseback distance of the plantation home. At nineteen he was admitted to the College of Engineering of the University of Texas, at Austin, Tex., from which he received the degrees of Bachelor of Science in Civil Engineering in 1892, Master of Arts in 1893, and Civil Engineer in 1900. He made a very distinguished scholastic record, earning membership in the Phi Beta Kappa and Tau Beta Pi fraternities. During the undergraduate period he worked each summer and in his spare time during the school years for the Texas Geological Survey.

In 1893 Mr. Thompson worked for the Pencoyd (Pa.) Bridge Company, resigning to become instructor in civil engineering at the University of Texas during the 1893–1894 session. He also served in this capacity during the 1897–1898 session. In the interim he worked for the Texas Railroad Commission, constructed a sewer system for Palestine, Tex., and worked for the Kansas City Southern Railway Company. He served as chief engineer for the Texas Railroad Commission from 1898 to 1908. He became chief engineer of the Wichita Falls and Northwestern Railway Company in January, 1909, and served as such until September, 1911.

Mr. Thompson was chief engineer of the California Railroad Commission from October, 1911, to May, 1913, resigning to accept membership on the Engineering Board, Bureau of Valuation of the United States rail lines, Interstate Commerce Commission, in charge of the Pacific District, San Francisco, Calif. This extremely important work lasted until October, 1921. Returning to Texas, he became chief engineer of the Wichita County Water Improvement District (Wichita Falls, Tex.) in charge of two large dams and a 40,000-acre irrigation system costing $4,500,000 which was completed in 1924. From 1924 to 1927 Mr. Thompson was co-chief engineer (with the late J. C. Nagle,[2] M. Am. Soc. C. E.) in charge of location, design, and construction of the Garza Reservoir Dam for the City of Dallas (Tex.) water supply, costing $5,000,000. In 1925 and 1926 he was a member of the firm of Thompson and Butler, Consulting Engineers, in San Francisco.

---

[1] Memoir prepared by Gibb Gilchrist, M. Am. Soc. C. E.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 93 (1929), p. 1878.

In 1927 the Texas Highway Department, being in need of reorganization, chose Mr. Thompson for the job and he earned the gratitude of a people by his courage and organizing ability in putting the department in order. Here his influence will be felt for many years. The work was strenuous and confining and when the organization had been perfected he returned to Dallas and resumed his consulting practice. He served as consultant to the Dallas Chamber of Commerce from 1928 to 1933 and from 1934 to 1938, particularly in connection with highway transport in the Dallas trade territory. During 1933 and 1934 Mr. Thompson served as state engineer for the Public Works Administration for Texas. He made a long-range plan for highways for Tarrant County, Texas. He served as chief engineer of the Wichita Falls and Southern Railway Company and as consulting engineer for the Brown County Water Improvement District. He made reports on power development for the Wichita County Water Improvement District and on a water supply for the City of Abilene, Tex. Appointed by the Governor in 1938, he served as engineer member of the Texas State Board of Health. There were many other lesser assignments.

Robert A. Thompson was married on December 21, 1897, to Evelyn Dickson of Cleburne, Tex. Seven children were born of this union—Frances, Robert Andrew, Jr. (Assoc. M. Am. Soc. C. E.), Elizabeth, Eleanor, Evelyn, Frederick, and Lucy, all of whom, with the pioneer wife and mother, survive. The writer knows that much of Mr. Thompson's success was due this wife who stood with him through every trial and whose every thought was for the welfare of her husband and children.

Mr. Thompson made some of his finest friends while living in Austin from 1900 to 1908. Frequently he played chess, bridge, and whist with four men who were to become famous within a decade, three as members of a wartime president's cabinet and one as his chief adviser. These men were Edward M. House, T. Watt Gregory, Albert S. Burleson, and David F. Houston.

Robert A. Thompson was endowed with a brilliant mind, which he constantly improved by study and hard work. He had an unquenchable and uncompromising honesty that was refreshing and inspired confidence. In passing, he has left a heritage of professional conduct and performance that is an inspiration to young engineers who have known and admired him. The engineering profession in Texas is better by reason of Robert A. Thompson's professional career and personal life.

The following editorial from the "Dallas Morning News" is appropriate:

> "A man of few words and many deeds, Robert A. Thompson, who died at Fort Worth Friday, typified the best in the modern engineering profession. From the time he was graduated from the University of Texas with high honors until the close of his professional career, his life was one of achievement, though his unassuming nature kept from him the public recognition that many another man would have gotten for a far less constructive career. A native Texan, he served his state faithfully, first as engineer to the Railroad Commission and later as State Highway Engineer under the administration of Governor Dan Moody. It was Highway Engineer Thompson, with the sponsorship of Governor Moody, who laid the basis for the present efficient department and its brilliant

record of accomplishment. Dallas owes Robert A. Thompson a lasting debt of gratitude."

Mr. Thompson was elected a Junior of the American Society of Civil Engineers on April 6, 1897; an Associate Member on October 4, 1899; and a Member on January 3, 1911. He became a Life Member on January 1, 1934.

CURTIS McDONALD TOWNSEND, M. Am. Soc. C. E.[1]

DIED MAY 26, 1941

Curtis McDonald Townsend, the son of Martin L. and Alice Sophia (McDonald) Townsend, was born in Brooklyn, N. Y., on March 22, 1856. He was graduated from the College of the City of New York in 1875, with the degree of Bachelor of Arts, at nineteen years of age, having completed a five-year course. He was undecided whether to study law or medicine but, taking the advice of a friend, he entered a competitive examination and received an appointment to the United States Military Academy at West Point, N. Y., on July 1, 1875. He was graduated in June, 1879, and was commissioned Second Lieutenant in the Corps of Engineers.

His first assignment as an officer was at Willets Point, New York, where he served until June, 1882, when he was promoted to First Lieutenant. He then became assistant engineer at Baltimore, Md., and Petersburg, Va., becoming assistant to the engineer commissioner in the District of Columbia on June 15, 1886. He returned to Willets Point in May, 1887, as Quartermaster of the Engineer Battalion there, in charge of the construction of buildings and the introduction of sewers and a water supply. In June, 1890, having been promoted to Captain, he was assigned to duty in Washington, D. C., in connection with the construction of the Washington Aqueduct.[2]

Captain Townsend was placed in charge of the Third Mississippi River District, at Memphis, Tenn., in July, 1896. In May, 1898, he was transferred to Grand Rapids, Mich., and placed in charge of construction there. While at Memphis he fell critically ill from typhoid fever, and he overheard the doctor tell his father, "We'll carry him out in the morning." This aroused his fighting spirit, and he said, "Not if I can help it." He recovered, but his body bore marks of the struggle throughout his life. With characteristic reticence, however, he said nothing. After he left Memphis one of his chief assistants paid this tribute: "Captain Townsend was a fighter."

After a brief tour of duty at Rock Island, Ill., he was assigned to the 3d Engineer Battalion in the Philippine Islands, where he served on the staff of the chief engineer, Philippine Division. During this time he was promoted to Major. While in the Philippines, he supervised the construction of military roads and the building of the Manila breakwater, and started wharfs for the City and Quartermaster Department; he also supervised the construction of harbors and wharfs in other parts of the islands.

[1] Memoir prepared by Col. James W. Skelly, M. Am. Soc. C. E., in collaboration with Col. John A. Laird, Cons. Engr., St. Louis, Mo., Lt. Col. Frank G. Jonah, Hon. M. Am. Soc. C. E., Lt. Col. Frederick W. Green, M. Am. Soc. C. E., and Maj. John J. Barada, Secy., Twelfth Engrs. Assn., St. Louis, Mo.

[2] *Who's Who in Engineering*, 1937, p. 1392.

Major Townsend returned to Washington, D. C., in May, 1906, as a member of the Board of Engineers for Rivers and Harbors. He went to Cleveland, Ohio, in February, 1908, and later to Detroit, Mich., meanwhile having been promoted to Colonel. In July, 1912, he became division engineer of the Western Division, at St. Louis, Mo. He also served as president of the Mississippi River Commission and as a member of the Experimental Towboat Board, formed to develop, through experiments, a suitable towboat for use on inland waterways.

Shortly before the outbreak of World War I, while stationed at St. Louis, he was called into consultation with the chief of engineers, concerning the organization of engineer regiments to construct and operate railways in France, in response to an urgent request from Marshal J. J. C. Joffre, who was then touring the United States. Colonel Townsend recommended that these regiments should have two battalions, one organized for construction, the other as a pioneer unit. Later this was modified, the pioneer unit being replaced by a railway operation battalion. Colonel Townsend was assigned the task of organizing one of these regiments in St. Louis, which was first called the Second, and later the Twelfth, Engineers. The officers were taken mainly from the Officers Reserve Corps, and the enlisted men from the railroads entering St. Louis from the south and southwest.

The Twelfth Engineers regiment sailed from New York City on July 28, 1917, and was assigned to the British on the Picardy front. It reached there on August 21, 1917, being among the first 30,000 American troops to reach France. The regiment was immediately placed in charge of the operation and maintenance of light railways near the Hindenburg line, and in due time built quite a number of extensions.

One day while Colonel Townsend was driving near the front, shells began dropping near-by. The chauffeur turned to him and said, "What shall we do Colonel, they are getting pretty close." Colonel Townsend replied, "Better keep on going, this is not a safe place."

Colonel Townsend was transferred to Paris, France, on February 12, 1918, to assume the duties of engineer representative on the General Purchasing Board for the American Expeditionary Forces. He left on the Regiment the impress of his own high standards of justice, democracy, steadfastness, and sound judgment. In October, 1918, he returned to the United States. For his World War services he was awarded the French decoration of Officer de le Legion d'Honneur.

On his return to the United States, he served for a time in the office of the chief of engineers. In December, 1918, he was again named division engineer of the Western Division, at St. Louis, and president of the Mississippi River Commission. He served in these capacities until February, 1920, when at his own request he was retired from active duty.

After retirement from active service, he lived for a time in Brooklyn. During this time he wrote a textbook for students on improvement of rivers and harbors, in the course of which he acquired a working knowledge of the Italian language in order to read references on the subject. Later he moved to Washington, D. C., where he continued to live until shortly before his death.

He was recalled to active service in the Corps of Engineers for two assignments. From December, 1923, until June, 1926, he served with the Rivers and Harbors Commission in New Orleans, La., and from July, 1926, until October, 1926, he served as Gulf district engineer in New Orleans, in charge of creating a 36-ft waterway in the Southwest Pass of the Mississippi River.

In the spring of 1927, the Belgian Ambassador to America requested Colonel Townsend to go to Brussels, Belgium, as a member of the International Board on Improvement of the Mouth of the Congo River. He did not go on to Africa for a personal inspection, but advised the Belgian Government as to what further data and surveys were necessary. When this information was assembled, in conference with Belgian and French engineers, a satisfactory report was formulated.

Colonel Townsend was a member of the Western Society of Engineers, the Engineers Club of St. Louis, and the Society of American Military Engineers. He was president of the latter society in 1934. He contributed numerous articles to engineering and technical journals, relating to commerce and improvement of navigable rivers. He had the ability to grasp a subject quickly; yet his considerations were deliberate, and his conclusions were reached only after a careful "estimate of the situation." Although respectful of the opinions of others, he would permit no motive of convenience or expediency to swerve him from what he believed to be his duty. He exemplified the highest type of honor and integrity.

As a boy, one of his hobbies was collecting stamps, which he continued throughout his life. He also paid considerable attention to geology, particularly of the Manhattan and New Jersey regions, from which he made quite a collection of stones. He was a scientific and skilful chess player.

He was by no means devoid of a sense of humor. When he was a Captain at Rock Island, two of his assistants were field officers in the National Guard of Illinois. One day, as he related to one of the writers, a messenger passed the word through the office, "Have the Major tell the Colonel the Captain wants to see him."

One of the field officers of the Twelfth Engineers paid this tribute: "He was a fearless soldier, a courteous gentleman, a staunch friend and an honorable man."

Colonel Townsend was never married. Since he had no family, he devoted his time to his profession and to his friends. In stature he was tall and erect, and of distinguished appearance.

He died on May 26, 1941, and was buried in Arlington National Cemetery.

Colonel Townsend was elected a Member of the American Society of Civil Engineers on November 1, 1893.

ROBERT WILLIAM WADDELL, M. Am. Soc. C. E.[1]

DIED APRIL 19, 1940

Robert William Waddell was born in Port Hope, Ontario, Canada, on October 31, 1859, the son of Robert N. and Angeline E. (Jones) Waddell. At the age of twenty two he was graduated from McGill University, in Montreal, Quebec, Canada, with the degree of Bachelor of Applied Science.

The early years of Mr. Waddell's professional life afforded him a wide and varied experience in engineering. His first interest was in railroad engineering, in the service of the Denver and New Orleans and the Denver, Texas and Fort Worth railroad companies. He next engaged in private practice from 1885 to 1887. In 1889 and 1890 he supervised the erection of the Castlewood Dam, in Colorado. After completing some government contracts, as deputy land surveyor, Mr. Waddell went to Kansas City, Mo., and during the years 1895, 1896, and 1897 he again turned his talents to railroad construction.

In 1898 Mr. Waddell served as engineer and superintendent of construction on the Hotel Baltimore in Kansas City. It seems almost symbolic that the structure that he built so well should continue, for the identical span of years as its builder, to serve the community so well and be such an outstanding landmark in the great transition period between 1900 and 1940.

In 1899 Mr. Waddell accepted a position as chief engineer of railroads for a mining company in Indian Territory, later Oklahoma, but returned to Kansas City the following year to become city engineer. During the period from 1900 to the date of his death, April 19, 1940, Mr. Waddell served the city as its city engineer for twenty-two years. Twice, during that period, he left the city service to engage in contracting. During the last few years of his life, he did considerable personal inspection of the many projects that he had envisioned and had seen materialize. Mr. Waddell's era saw the reconstruction of his community in the changes necessitated by the introduction of the automobile, and its attendant traffic problems, and also the general modernization of all utilities that occurs when a small community develops into a large metropolitan center. The personal interest which Mr. Waddell had in his work, and the outdoor life made possible by his personal inspections, undoubtedly contributed much to the prolongation of his life during that period when his health was failing slowly.

In addition to his membership in the Society, Mr. Waddell was an honored member of the Engineers' Club of Kansas City, the American Road Builders Association, the American Society for Municipal Improvements, and the National Conference of City Planning. His interest in civic affairs was as great as that in his profession and he also held membership in the Knife and Fork Club of Kansas City, The Safety Council, The Citizen's League, and the City Club of Kansas City. During his many years of service in Kansas City, Mr. Waddell was known and loved by engineers and contractors and, for at least a generation, he was to them "Uncle Bob."

---

[1] **Memoir prepared by Arthur C. Everham, M. Am. Soc. C. E.**

As a pastime, Mr. Waddell was an ardent philatelist, and he had an unusually fine collection of stamps, some of considerable value. He said that he developed his interest in stamp collecting by cleaning out the wastebaskets in his father's office. He specialized in Canadian and United States stamps and owned one ninety-cent United States stamp which was so rare that he was unable to find any one who could determine its value.

Mr. Waddell was an Episcopalian and was a member of St. George's Church, which he served for many years as Vestryman. He was most generous with his charities, and many a younger man can remember his readiness to help out in times of financial distress.

His death at the age of eighty concluded a long and useful life during which he established a standard in municipal service that always will be a goal for those who follow him. He left a family consisting of Sarah E. Waddell, to whom he was married on November 24, 1897, and two sons, Gerald Needham and Robert Douglas Waddell. Many tributes have been paid Robert W. Waddell, but none was greater than that expressed by the head of one family who said he would indeed be very happy if he could raise his two boys to be as fine men as Mr. Waddell had raised his sons to be.

Mr. Waddell was elected a Member of the American Society of Civil Engineers on September 4, 1901.

EDWARD WEGMANN, M. Am. Soc. C. E.[1]

Died January 3, 1935

Edward Wegmann was born in Rio de Janeiro, Brazil, on November 27, 1850. His ancestors had settled in the City and Canton of Zürich, Switzerland, where they became a very distinguished family. The records show that one, A. Wegmann, moved from the City of Tagelschwangen, Switzerland, to the City of Zürich in 1469. Lewis Edward Wegmann, the father of Edward Wegmann, was born in Steckborn, Switzerland, on March 14, 1814, and came to New York, N. Y., when he was seventeen years old. There he soon obtained a position with the firm of De Rham, Iselin and Moore. When he was twenty-three years old he accepted an offer to become a partner of Mr. Daniker of Zürich, who was in the export and import business in the City of Rio de Janeiro. Lewis Wegmann went to that city in 1837, and remained there for about fifteen years. During an epidemic of yellow fever, he and his wife (the former Mary W. Sand) both contracted the disease, so they returned to New York City and Mr. Wegmann became a partner of the well-known firm of A. C. Rossire and Company. During the panic of 1857 this firm suffered heavy losses, which caused him to sever his connection with it and go to Galveston, Tex., where he went into business under the name of Wegmann and Parizot, shortly before the outbreak of the Civil War. Before leaving for Texas, however, he took his family to Zürich. He left his wife and four children there until 1866, when he took them back to New York City. He again engaged in business in that city until his death in September, 1895. His wife passed away in April, 1896.

---

[1] Memoir prepared by T. Kennard Thomson, M. Am. Soc. C. E.

Their son, Edward Wegmann, born during the family's stay in Brazil, received his first education in a private school in Brooklyn, N. Y., from his sixth to his ninth year. From his ninth to his sixteenth year, he attended the public schools of Zürich. On returning to America he spent two years in the Polytechnic Institute of Brooklyn, and then became a clerk in his father's business for a short time. Not finding the work congenial, he decided to become a civil engineer. He was graduated from New York University, in New York City, in June, 1871, with the degree of Civil Engineer.

During the next twelve years he was engaged on the construction of railroads. He started as axman and was then chainman on the New York, West Shore, and Chicago Railway during August, September, and October, 1871. From January to December, 1872, he was a rodman on the New Haven, Middletown and Willimantic Railway. He acted as assistant engineer on the same railroad from January to December, 1873. For the greater part of 1874, Mr. Wegmann was working in the Wyandotte (Mich.) Rolling Mill, and in the Machine Shop, learning the manufacture of iron (there was no steel in those days).

From March, 1875, to August, 1877, Mr. Wegmann, in partnership with the late Robert W. Creuzbaur,[3] M. Am. Soc. C. E., a mechanical engineer, developed a new steam engine, and some other inventions, first at their own shop, and then, during 1876, at the Danforth Locomotive Works in Paterson, N. J. From November, 1877, to June, 1878, Mr. Wegmann was engineer for the Keystone Bridge Company (a Carnegie subsidiary), in charge of building foundations and superstructures of the Sixth Avenue Elevated Railway in New York City. From June, 1878, to August, 1879, he was assistant engineer on the Ninth, Second, and Third Avenue Elevated railways, all in New York City.

He was on the engineering staff of the New York and New England Railway Company from January to May, 1880, when he became assistant engineer on the location of the Ohio River and Western Railway. From August, 1880, to January, 1884, Mr. Wegmann was resident engineer on the construction of The New York, West Shore and Buffalo Railroad, in charge of 14 miles of work near Haverstraw, N. Y., and then 16 miles in Genesee County, New York.

In 1884 Mr. Wegmann became assistant engineer on the New Croton Aqueduct (New York), engaged in the office of the chief engineer. The first duty to which he was assigned was to make studies for the design of the proposed Quaker Bridge Dam, which was to be built across the Croton River. This structure was to have a height of 297 ft above the lowest foundation. This was to be a monumental structure, more than 100 ft higher than any masonry dam built up to that time.

After a thorough study of the subject, material for which was found mainly in the professional memoirs of French Engineers as published in the

---

[3] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 90 (1927), p. 1160.

Annales des Ponts et Chaussées, he arrived at a very simple formula for designing masonry dams. It was used for the New Croton Dam (originally called the Quaker Bridge Dam) and for some other very high dams in America.

In 1888 the first edition of Mr. Wegmann's monumental work on *The Design and Construction of Dams,* including treatments of masonry, earth, rock-fill, timber and steel structures, and principal types of movable dams, was published by John Wiley and Sons, Inc. The eighth edition of this great book (740 pages, 9 by 12 inches, with many illustrations, and, in addition, 111 plates) appeared in 1927. It gives a full explanation of the simple analytical method he devised for the New Croton Dam and a description of the principal masonry dams, completed before 1888, in Spain, France, and other foreign countries. He was working on the ninth edition before he died.

In 1885 Mr. Wegmann was made division engineer of the Manhattan Section of the New Croton Aqueduct, which included the tunnel under the Harlem River and the section from 179th Street to 135th Street, the terminal gate-house at this street, and eight pipe lines 4 ft in diameter that terminated at the Central Park Reservoir.

Following this assignment, in 1892 Mr. Wegmann was transferred to the Croton watershed and placed in charge of the Croton River Division of the New Croton Aqueduct. This included the construction of the Muscoot Dam (about nine miles upstream from the New Croton Dam) and all the changes of highways and railroads made necessary by the construction of the Croton Reservoir. This work naturally caused Mr. Wegmann to take a great interest in the early history of the New York water works, so he wrote another monumental book on *The Water-Supply of the City of New York,* covering the years 1658 to 1895. The book was published in 1896 by John Wiley and Sons, Inc.

Before this book appeared, Mr. Wegmann was engaged by the Committee of the Legislature in charge of the exhibit of the State of New York at the Columbian Exposition held in Chicago, Ill., in 1892, to prepare for this Exposition a "Description of the Waterworks of the City of New York," illustrated by plans and photographs. As a result of this exhibit the Aqueduct Commissioners of the City of New York (in whose service Mr. Wegmann remained while preparing the exhibit) received a diploma from the Commissioners of the Columbian Exposition. Mr. Wegmann also was awarded a diploma of honorable mention for his work.

After twenty years spent in the field in charge of this important construction for the Aqueduct Commissioners, he was transferred from the Croton Division to the headquarters in New York City. He was then instructed to write the final report of the works completed under the direction of these Commissioners, from 1895 to 1907, when the New Croton Reservoir was completed. This report, which is complete with practical and technical details, was published by the Commissioners in 1907, in which year they appointed Mr. Wegmann their consulting engineer. Three years later he was promoted to the position of chief engineer for the Commission; he was the last person to hold this title.

In the same year, however, as the projects constructed under their supervision were about completed, the Commission was abolished by Act of Legislature and the employees were transferred to the Department of Water Supply, Gas and Electricity of the City of New York. Mr. Wegmann then was appointed consulting engineer for the Bureau of Water Supply of this Department, and held the position for four years, when he resigned to open an office as a consulting engineer. He had many clients in various parts of the world, advising them especially on dams and water works.

Another of his books was *Conveyance and Distribution of Water for Water Supply; Aqueducts, Pipe-Lines and Distribution Systems,* published by D. Van Nostrand Company in 1918. In 1890 Mr. Wegmann and C. J. Bates published a pamphlet on "A System of Rapid Transit for the City of New York." This was a comprehensive plan for a construction three decks high, consisting of one subway with two elevated structures above it, each having two railroad tracks, or six in all. They proposed one line between Third and Fourth avenues, and another line between Ninth Avenue and the North River.

In 1893 Mr. Wegmann published a *Catalogue of the Illustrations of the Water-Supply of the City of New York.* He contributed many articles to the press and to various societies. For the American Society of Civil Engineers alone, he took part in writing or discussing some twenty-five papers, on dams, railroads, elevated railroads, pneumatic plants, water mains, and surveying in tunnels.

From July, 1918, to January, 1920, Mr. Wegmann was retained by The New York and New Jersey Harbor Commission (later The Port of New York Authority), making estimates of the cost of constructing subways, elevated railroads, and tunnels for freight service. For this Commission he wrote a report on "The Water Supply of the Metropolitan District of New York," including part of New Jersey. It contained estimates of existing available resources of water supply and probable consumption until 1975.

For the last time Mr. Wegmann reentered the service of the City of New York in 1920. He served until 1925, when he retired with a pension for life.

In 1922 Mr. Wegmann was honored by The International Congress of Engineers, which was held that year in Rio de Janeiro, the city of his birth. The Commission of the four American societies at the Congress asked him to write a paper on "The Design of Masonry Dams." The Commission also sent to The Engineering Society of Rio de Janeiro a copy of Mr. Wegmann's book on dams. As a result, Mr. Wegmann was unanimously elected an Honorary Member of The Engineering Society of Rio de Janeiro.

He was also a member of The New England Water Works Association, The American Water Works Association, and The American Society of Engineering Contractors.

Mr. Wegmann and Albert Nelson Aeryns developed a new formula, based on about 1,000 tests, to determine the flow of water in new and old cast-iron pipes. They also contracted with The Research Association of Cast Iron Pipe and Foundry Companies to prepare tables for the flow of water in clean and old cast-iron pipes that varied in diameter from 4 in. to 60 in.

Mr. Wegmann lectured at Harvard University (Cambridge, Mass.), Yale University (New Haven, Conn.), and other leading universities, and at many other gatherings of professional men. His books have been translated into several foreign languages. He spoke fluently four languages: English, French, Italian, and German. Probably the reason he did not speak Portuguese was because he left Brazil when he was about one year old.

The *American Swiss Gazette,* published in New York City, printed in 1931 a number of biographical sketches of outstanding men of Swiss birth or ancestry, including a very fine one of Edward Wegmann. The publishers were justifiably proud of his great record. (The writer wishes to express his thanks for having had the opportunity to make many extracts from that fine paper for this memoir.)

He spent the last years of his life in Yonkers, N. Y., and in 1927 wrote a comprehensive letter to *The Yonkers Herald* indorsing the late Mayor Thomas F. Larkin's efforts to obtain more water from New York City for Yonkers. He made some good suggestions on the subject.

He became a Mason on April 26, 1910, and became a charter member of Fernbrook Lodge No. 898, F. and A. M., at Yonkers, in June, 1912. He was a regular attendant at the meetings of that Lodge until a short time before he died, and was given a Masonic funeral. He was also a good Episcopalian and attended St. John's Church in Yonkers. Mr. Wegmann also was an excellent musician and at the age of nine received an unusually fine violin, which he played well all his life.

On May 6, 1901, he was married to Charlotte H. Drummond. Their son, Charles Edward Wegmann, was born on February 11, 1905, and became a successful businessman, importing and exporting rubber. A daughter, Cecile D. Wegmann, born in September, 1907, is a fine concert pianist. Mr. Wegmann must have been a devoted son and brother, and he certainly was a devoted and proud husband and father. Furthermore, he was a true citizen and a faithful friend.

Edward Wegmann was the most outstanding authority of his time on the design and construction of dams and water works. In addition, he had an unusually broad experience in many other branches of engineering, as is evidenced by the printed works he left behind him and the memory of those who knew him.

Mr. Wegmann was elected a Member of the American Society of Civil Engineers on March 7, 1888, and cherished that membership as long as he lived.

LESLIE CLIFFORD WHITTEMORE, M. Am. Soc. C. E.[1]

DIED JANUARY 13, 1941

Leslie Clifford Whittemore was born at Milford, Mass., on April 22, 1885. His father, the late George H. Whittemore, lived in Milford, and was both a jeweler and an electrical contractor. His mother, Minna L. (Mann) Whittemore, is the daughter of Capt. Elbridge Mann, who was a shoe manufacturer of Milford and one-time representative in the Massachusetts State Legislature.

---

[1] Memoir prepared by Langdon Pearse and Norval E. Anderson, Members, Am. Soc. C. E.

Mr. Whittemore's early life was spent in Milford, where he attended the public schools. In June, 1907, he was graduated from the Massachusetts Institute of Technology, in Boston, Mass., with the degree of Bachelor of Science in Sanitary Engineering.

His first engineering experience was with the Massachusetts State Highway Commission, on surveys for state roads, during the summer of 1906. After graduation from the Massachusetts Institute of Technology, he was employed as a draftsman in the building department of the American Brass Company, at Waterbury, Conn., for about six months. His first sanitary engineering position was that of assistant engineer for the Massachusetts State Board of Health, from December, 1907, to January, 1909, on examinations and reports for water supply, sewage treatment, and stream pollution. From January to May, 1909, he was assistant chemist at the Washington, D. C., Filtration Plant on chemical, bacteriological, and microscopic analyses of water for control of plant operation.

In May, 1909, Mr. Whittemore joined the Board of Water Supply, in New York, N. Y., as assistant engineer in the Northern Aqueduct Department, where he served until July, 1910, as assistant to the department engineer. From July, 1910, to May, 1911, he had charge of construction at Shaft No. 5 of the Moodna Siphon, a deep-rock tunnel 14 ft in diameter. Thereafter he served as principal office assistant to the department engineer until October, 1912.

For twenty-nine years Mr. Whittemore was associated with The Sanitary District of Chicago, Ill., beginning October 15, 1912, at a time when the Sanitary District was investigating methods for treating the rapidly increasing volume of domestic sewage and industrial wastes that was overloading the canal dilution system. For several years he was concerned with the operation of the various sewage testing stations on industrial wastes, reports on the tests, and the study of preliminary plans for treating industrial wastes, as well as plans for intercepting sewers and studies for the treatment of sewage for the entire Sanitary District.

When actual work began, in 1919, Mr. Whittemore, as principal assistant to the sanitary engineer, was active in the design and preparation of plans and specifications for the Calumet and Des Plaines River sewage treatment works. He gradually took over the responsibility for this part of the work until, in 1925, he was placed in charge of the separate division of Sewage Treatment Plant Design. In 1930 he was appointed engineer of design, with general supervision and coordination of the various design divisions of the Sanitary District. He continued in this capacity until his death.

Mr. Whittemore was active throughout his connection with The Sanitary District of Chicago in the development of its sewage treatment program, from the early experiments through the studies and reports on a general scheme; studies and experimental work on treatment processes; preparation of data for litigation and for the review of consulting engineers; and the design, preparation of plans and specifications, and construction of all the sewage treatment plants. Under his supervision, as engineer of design, were prepared the plans for the four major plants, Calumet, North Side, West Side, and Southwest. Before he died the initial units of the Southwest Sewage Treatment Plant were put into operation, the largest sewage treatment plant in the world.

As an engineer, Mr. Whittemore was known for his painstaking attention to detail and thorough analysis of basic data and the alternatives available, as well as for the soundness of his conclusions. His decisions and judgment were universally respected by his associates. He applied himself unsparingly in time and effort to the problems at hand, sometimes to the detriment of his health. Always considerate of his associates and subordinates, he was not impatient with those of lesser ability. Although the author of a number of technical articles and papers presented to the Society, he wrote little, considering his knowledge and authority, because of his modesty and constant application to his work. He was a member of the Society's Committee on Activated Sludge Practice.

Mr. Whittemore was a member of the Central States Sewage Works Association. In addition to his professional work, he was interested in athletics. He was a great reader, especially of history and travel, and a lover of good music. He was a member of the Congregational Church.

In 1936 Mr. Whittemore suffered a severe heart attack, from which he soon recovered and was able to resume his duties. However, there were succeeding attacks. In the late summer of 1940, his condition became such that he was confined to his home, in Chicago, where he died on January 13, 1941.

He was married on June 4, 1913, in Poughkeepsie, N. Y., to Lucile Marion Taber of that city. He is survived by his widow; his only son, Robert; his mother; and his sister, Mildred E. Whittemore.

Mr. Whittemore was elected a Junior of the American Society of Civil Engineers on May 3, 1910; an Associate Member on June 24, 1914; and a Member on July 11, 1921.

JOSEPH WHITE WILLIAMS, M. Am. Soc. C. E.[1]

DIED FEBRUARY 3, 1941

Joseph White Williams was born in Milan, Erie County, Ohio, on October 20, 1879, the son of Daniel Newton Williams and Sophie (White) Williams. His early life was spent in and about Milan, where he was graduated from the Milan High School in 1897.

In 1898 he enlisted as a private in the 52d Iowa Volunteer Infantry in the Spanish-American War. On the cessation of hostilities, after receiving his discharge, Mr. Williams held various minor positions on railroad location and construction until 1903. From 1903 to 1906 he served in the capacity of transitman and assistant engineer on location and construction for the Atchison, Topeka and Santa Fe Railway Company in New Mexico and California. In 1907 he was appointed assistant chief engineer of the San Francisco and Northwestern Railway Company with headquarters in San Francisco, Calif. Later, when the Northwestern Pacific Railroad Company was organized, Mr. Williams continued in this capacity on all the vicissitudes of the Eel River Canyon construction in California. His brilliant handling of this particularly difficult piece of construction work earned for him the promotion to chief engineer of the Northwestern Pacific Railroad Company in July, 1914.

---

[1] Memoir prepared by H. M. Smitten, M. Am. Soc. C. E.

Mr. Williams was selected for and accepted a commission as Major in the 18th Engineers, United States Army, in May, 1917. He arrived at American Lake, Wash., on June 19, 1917. After a period of about a month, during which time the regiment was thoroughly organized and placed on a war basis, it left American Lake for Hoboken, N. J. On August 23, 1917, the regiment sailed for France, one of the first of the United States armed forces bound for foreign parts. On arrival at Le Havre, France, on August 29, 1917, work was quickly begun on the railroad yards at San Sulpice and Bassens and later on the Bassens docks. Major Williams played a prominent part in the construction of these projects and later, when Col. J. B. Cavanaugh was called away, was promoted to Lieutenant Colonel of the regiment.

Colonel Williams returned to the United States in July, 1919, and resumed his position as chief engineer of the Northwestern Pacific Railroad Company. He retained this position until August, 1921, when he was called to the Western Pacific Railroad Company as its chief engineer. The latter position he held until his death in February, 1941.

Colonel Williams held a commission in the Engineer Reserve, U. S. Army, from 1920 until his death. He was a charter member of the Society of American Military Engineers, and was president and director of the San Francisco Post. He was also president of the San Francisco unit of the Association of the Army of the United States and of the Army and Navy Club of San Francisco.

In 1902 he was married to Eliza Hunt who, with a son, Joseph H., and a daughter, Mary (Mrs. J. F. Loughery), survives him.

Colonel Williams was elected a Member of the American Society of Civil Engineers on January 13, 1930.

RONALD BLAIR WILLS, M. Am. Soc. C. E.[1]

DIED OCTOBER 31, 1941

Ronald Blair Wills was born on September 8, 1896, in Calusa, Calif., the son of James and Katherine (Blair) Wills. The family moved to Evansville,

---

[1] Memoir prepared by F. W. Epps, M. Am. Soc. C. E., and Ross C. Keeling and W. S. McDaniel, Assoc. Members, Am. Soc. C. E.

Ind., in October, 1896. Mr. Wills attended grade school and high school at Evansville, and after graduation from high school entered the Missouri School of Mines and Metallurgy at Rolla, Mo., enrolling in the course in civil engineering. He was graduated from this school in 1920 with the degree of Bachelor of Science in Engineering.

At the end of his junior year, in 1919, he was employed for the summer as draftsman with the Southwestern Engineering Company at Hutchinson, Kans. After graduation in 1920, he went back to Hutchinson and was employed by Reno County, Kansas, as draftsman from May to August, 1920. He worked on highway plans for federal-aid paving projects in that county.

In August, 1920, he moved to Garden City, Kans., and from that date to April, 1922, was employed by Finney County, Kansas, as office engineer and field engineer on federal-aid grading and paving projects throughout that county. In April, 1922, he was given the position of resident engineer on the various highway projects under construction in that county, continuing in this position until March, 1923. At that time he moved to Wellington, Kans., and was given the position of field engineer and office engineer for Sumner County, Kansas. This involved the designing of highway projects in that county and the field work connected with their construction.

In April, 1924, he was given the position of resident engineer on highway paving projects in Jefferson County, Kansas. During this period he resided at Oskaloosa, Kans. The highway paving consisted of concrete, brick, and bituminous macadam.

The period from 1920 to 1925 marked the start of highway construction in the State of Kansas in the various counties in which he worked, and the projects on which he was employed covered many of the first federal-aid highway projects constructed in Kansas. They marked the beginning of highway construction in this state. The highway laws of Kansas were such that federal-aid highway projects were initiated by the counties, the counties making their own plans and letting the contracts. The work was done under the supervision of what was then the Bureau of Public Roads and a skeleton organization of the State Highway Commission of Kansas. In May, 1925, the State of Kansas was divided into six highway divisions, and, because of Mr. Wills' wide experience throughout the beginning of highway construction in Kansas, he was sent to Hutchinson as division engineer in the Fifth Highway Division, with supervision over highway work in eighteen counties. He continued in this capacity until April, 1934, having an outstanding record in this position. During the time he was division engineer with the Kansas Highway Commission, the state, through a constitutional amendment, took over complete control of all the state highways, thereby relieving the counties of their connection with highway construction and maintenance on the state highway system. Mr. Wills took an active part in solving the problems of the organization of the State Highway Commission during this period of change from the county system of control of highways to full control by the state, and his organizing ability had much to do with the final organization of the State Highway Commission of Kansas.

In April, 1934, Mr. Wills was transferred from his position as division engineer to the headquarters office at Topeka, Kans., and was given the position of assistant maintenance engineer. This was during the early period of bituminous road construction in Kansas, and he was brought into headquarters because of his original work in the construction and maintenance of this type of road, the first project of this type having been constructed under his supervision while he was division engineer.

In August, 1934, he was given the position of engineer of construction and served in that capacity until January, 1936. At this time he was given the position of engineer of highway planning and organized this department, continuing in that capacity until May, 1937, at which time he became engineer of design.

Mr. Wills was appointed state highway engineer in April, 1939, and continued in that capacity until his death. Because of his wide experience in the field and in the various headquarters departments of the State Highway Commission, he was especially well qualified for the position of state highway engineer. His professional career was an example of devotion to public work. He took an active part in the meetings of the American Association of State Highway Officials, the Mississippi Valley Conference of State Highway Departments, and local state highway meetings. During the time he served as state highway engineer, much was accomplished by the Department in the establishment of better public relations, due principally to his character and reputation as an engineer and to his personality and outstanding ability to make friends.

He was a member of the Kansas Engineering Society and the Masonic Lodge, and was a trustee of the Westminster Presbyterian Church of Topeka.

Mr. Wills was married on May 25, 1923, to Kathryn Brown, who, with two daughters, Sara Frances and Shirley Ann, and his mother, survives him.

Mr. Wills was elected an Associate Member of the American Society of Civil Engineers on April 23, 1928, and a Member on December 13, 1937.

WALTER SCOTT WINN, M. Am. Soc. C. E.[1]

Died May 31, 1941

Walter Scott Winn was born near Winchester, Ky., on May 15, 1869, the son of Joshua Nicholas and Ellen (Poston) Winn. His early education was received in schools at Winchester and at Kentucky University, at Lexington, Ky., where he was a student in the civil engineering course for two years. Immediately after departing from the university, he was associated for two years (until June, 1889) with Thompson, Hall, and Bosler, Consulting Engineers, at Chattanooga, Tenn. During this time he developed his engineering education by constant study, reading, and extensive and varied experience. This was further amplified by continuation of his studies at Lehigh University, at Bethlehem, Pa., which he attended from 1889 to 1891.

---

[1] Memoir prepared by Lee G. Warren, M. Am. Soc. C. E.

In May, 1891, he joined the civilian staff of the U. S. Engineer Corps, with which he identified himself, except for brief periods, until July, 1918. Starting as a levelman on the Tennessee River, he was employed by the Chattanooga (Tenn.) Engineer District under the late Col. George W. Goethals,[2] M. Am. Soc. C. E., who became famous as the builder of the Panama Canal. He rose to assistant engineer in 1894. He continued in that capacity until 1909. In these various assignments he was in charge of dredging operations and open channel improvements (1894 to 1898), and construction of Colbert Shoals Lock on the Tennessee River (1898 to 1901). From 1901 to 1909, his work covered the operation and maintenance of Muscle Shoals Canal, and design, construction, and repair of construction equipment and machinery for improvement of the Tennessee and Cumberland rivers.

In an intermission from December, 1909, to September, 1911, Mr. Winn was general manager of the North Alabama Construction Company, engaged upon construction of irrigation, drainage, and lock and dam projects. From the latter date, following his first period of private practice, and ending February, 1912, he was employed by the Alabama Power Company as chief of surveys on investigation of power sites, which concluded in May, 1913. From 1920 to 1921 he was engaged in private engineering practice in Chattanooga.

In May, 1913, he returned to the Engineer Corps, as principal assistant engineer for the Tennessee River, continuing in that assignment until 1917. He had charge of construction on the river and of surveys, investigations, and preliminary plans for combined scheme for navigation improvement and power development at Muscle Shoals, Ala. From the middle of 1917 to July 31, 1918, he held the appointment of district engineer for the Chattanooga and Nashville U. S. Engineer District. In 1918, he was appointed disbursing officer and assistant engineer, Florence District, U. S. Engineer Corps, on the construction of Wilson Dam, in Alabama.

He was engaged in almost every phase of river work, but particularly in the extensive operations of open channel improvement by dikes and dredging. One of the outstanding accomplishments of Mr. Winn was during the period of 1915 and 1916 when, as assistant to the U. S. Engineer, he prepared the report of the Tennessee River between Browns Island, Ohio, and Florence, Ala., which included the projects of Dams No. 1 and No. 2 (Wilson Dam) and Dam No. 3 (Wheeler Dam). This is House Document No. 1262 and the basic survey and report for the improvement which has since been completed in the Muscle Shoals section.

In August, 1918, he became associated for a year with the Air Nitrate Corporation, on what was probably one of his most important jobs, as works engineer and camp supervisor at U. S. Nitrate Plant No. 2, at Sheffield, Ala. More than 20,000 employees were under his supervision.

In July, 1919, he became general manager of the Southland Exploration Company, mining and milling zinc in eastern Tennessee. He continued in that position until July, 1921, when he was appointed assistant to the chief engineer of the Alabama Power Company, carrying out that assignment until April, 1929. Here he supervised all inspection of concrete on the construction of Mitchell Dam, in Alabama, and other large projects.

---

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 93 (1929), p. 1813.

He again became associated with the U. S. Engineer Corps of the War Department in September, 1929, continuing in that association until March, 1940. He was assigned, in succession, to the Cincinnati (Ohio) and Huntington (W. Va.) Districts. He had charge of various studies and investigations on the Ohio River and several tributaries. The official assignment was supervising the "Studies and Reports Section of the Cincinnati Division."

Walter Scott Winn was always called the "Major" by his friends and close associates. He was a Major in the Engineer Reserves, but the title was really coupled with great respect and feeling of endearment by those who knew him well. He was always affable. His personality was attractive and his bearing dignified. Major Winn was deeply considerate toward his junior associates, being ever ready to assist them in their problems. He had a splendid character with the mark of the "old school." Major Winn's experience was particularly wide and long in river improvements. He had several assignments which were very intensive; for example, his work at Mitchell Dam. The details of his experience records describe the scope of his work.

Major Winn was married to Lena McDermott on September 11, 1894. He is survived by a daughter, Martha (Mrs. C. E. Parker), and two sons, Herbert P. Winn, Assoc. M. Am. Soc. C. E., and Lt.-Col. W. S. Winn, Jr.

Major Winn was elected an Associate Member of the American Society of Civil Engineers on October 6, 1897, and a Member on October 1, 1926.

ALBERT JOSEPH WISE, M. Am. Soc. C. E.[1]

DIED FEBRUARY 3, 1942

Albert Joseph Wise was born at Suffield, Ohio, on December 18, 1871, the son of Bernard Wise and Rosina (Knapp) Wise. He was educated in the public schools of Suffield, attended St. Josephs Preparatory School at Ada, Ohio, and was graduated in 1898 from Ohio State University, at Columbus, with a degree of Civil Engineer. After graduation he was employed as roadmaster on the Baltimore and Ohio Railroad.

In 1902 he came to Texas on a vacation trip, and liked the state so well that he went back north only to resign. He returned to Texas that same year, settling in Houston, where he remained until his death.

After several jobs, including one with the Dayton Goose Creek Railway Company, he formed a partnership in 1909 with the late Joseph Milton Howe,[2]

---

[1] Memoir prepared by Charles R. Haile, M. Am. Soc. C. E.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 102 (1937), p. 1569.

M. Am. Soc. C. E. The firm of Howe and Wise had a prominent place in the building of Houston and the great Southwest.

They served Harris County as county engineers from 1911 to 1914 and from 1917 to 1929, and again as consultants on bond-issue work in 1935 and 1936. The excellent network of roads and bridges in Harris County stand today as a monument to this firm.

An excerpt from an editorial of a Houston newspaper expresses the high regard in which Mr. Wise was held in his community.

> "In 1909 he formed a partnership with the late J. Milton Howe who died in 1937. The partnership was so successful that most Houstonians immediately think of the firm when either name is mentioned.
>
> "The firm served Harris County as County Engineers for many years. Their work was so noteworthy, particularly their highway construction methods, that they became nationally famous. Two new methods of road construction developed in Harris County roads by the partners were adopted as standard practice all over the country.
>
> "Besides their outstanding engineering achievements, the partners were respected for their professional integrity and high standard of ethics. During their many years of service as County Engineers, they successfully resisted all forms of political pressure and maintained a notable reputation for honor and skill."

This high standard of ethics and his pride in the engineering profession is well expressed in an interview he gave, published in the *Houston Magazine:*

> "To analyze and search for the truth is the function of the engineer. In the measure of his mental equipment and training for analysis of the natural resources and conditions in relationship to the present and future material needs of his fellow man, will he be able to set down the true facts for the guidance of others. Essentially, the engineer is a pathfinder in human progress."

It can be said truly that A. J. Wise has left his mark in his community, both in the engineering works he planned, designed, and constructed and in the inspiring memory of his christian character, high ideals, and friendly and wise counsel, which lies deep in the hearts of his friends, colleagues, and the young engineers whom he guided.

A. J. Wise always took an active part in the civic and social life of his community and is well known and highly regarded as a citizen.

He was a charter member of the Houston Engineers Club, serving as one of its first directors and later as President. He was a member of the Knights of Columbus, Holy Name Society of Holy Rosary Church, and, until his health forced his resignation, a member of Houston Rotary.

Mr. Wise was married on September 30, 1914, to May Cushman, who survives him.

Mr. Wise was elected a Member of the American Society of Civil Engineers on September 3, 1912. He became a Life Member in 1942.

GEORGE PILLSBURY WOOD, M. Am. Soc. C. E.[1]

DIED OCTOBER 15, 1940

George Pillsbury Wood was born in Lebanon, N. H., on March 2, 1866. His father, James Wood, and his mother, Rebecca (Pillsbury) Wood, both natives of New Hampshire, were representatives of that energetic, clear-thinking, and public-spirited stock that forged New England into a political and industrial power far beyond its natural advantages.

The common school, the town meeting, the unfailing industry, and the all-round mechanical skill required to wrest a living and an education from a New England hill farm found their reflection in a notable engineering mind and in a man whose character won the love and respect of all his associates.

Beyond his common school education, Mr. Wood had only part of one year in attendance at Kimball Union Academy at Meriden, N. H., before entering the New Hampshire College of Agriculture and Mechanic Arts, then a department of Dartmouth College at Hanover, N. H. He was graduated first in his class with the degree of Bachelor of Arts in 1886. In 1888 he entered the Thayer School of Engineering of Dartmouth College for a two-year graduate course, which he did not finish. He left college at the end of the first year to undertake the practical work of life. Suffice it to record that in 1903 Dartmouth College conferred upon Mr. Wood the degree of Civil Engineer for distinguished services already performed, and in doing so honored itself in recognizing the worth of the engineer and the man.

Mr. Wood entered the drafting room of the King Bridge Company at Cleveland, Ohio, in the spring of 1889 and three months later took service with the late Gustav Lindenthal,[2] Hon. M. Am. Soc. C. E., as rodman on a survey contemplating the development of the then Maryland Central Railroad into a coal line from the anthracite coal fields of Pennsylvania to the City of Baltimore, Md. The funds for this project failed in the latter part of the year 1889, and in November of that year Mr. Wood went to Roanoke, Va., where he found immediate employment with William M. Dunlap, city engineer, under whose direction he served for four years.

His first assignment was the topographical survey and construction of a real estate project at Craig City, Va. Although this undertaking was in advance of the requirements of the region, the experience served to impress upon Mr. Wood the needs of comprehensive municipal planning.

Returning to Roanoke in 1891, still with Mr. Dunlap, Mr. Wood was called upon to prepare plans for a survey of the city that were unique in two particulars. First, Mr. Wood prepared an ordinance for the city council which not only provided for the survey and its expense, but also gave authority to the results of the survey in the location of streets and property lines, together with means of adjusting claims which might arise later. This ordinance was adopted as submitted, and the procedure has been justified by its results. Second, Mr. Wood prepared the plans for a precise triangulation survey, which gave a base for accurate traverse surveys upon which were hung not only the street and property limits, but also the topographical survey for the locations of city extensions with their required drainage systems. All positions of this survey were expressed in rectangular coordinates based on a central meridian established by careful observations on Polaris, with triangulation and traverse points practically located and permanently fixed.

---

[1] Memoir prepared by George P. Bard, M. Am. Soc. C. E., in collaboration with Robert A. MacGregor, M. Am. Soc. C. E., and C. H. Rice, Research Engr. (*Retired*), New York Central R. R. Co., Hillsdale, N. Y.

[2] For Memoir, see *Transactions*, Am. Soc. C. E., Vol. 105 (1940), p. 1790.

This was the work of an engineer two years out of college who, with few precedents, developed plans that should be standard practice and put the entire project into effect. A description of this survey with its enabling ordinances was sent, in 1891, to the *Engineering News* and was received with such appreciation by the late George H. Frost,[3] Assoc. M. Am. Soc. C. E., then editor, that an advance article was printed and mailed to five hundred city engineers in the United States as a procedure worthy of thorough study by the profession. Before this survey was complete, Mr. Wood read a paper before the Association of Engineers of Virginia, of which he was a charter member, describing the methods and results of the triangulation and traverse surveys. The paper is still good reading for any engineer planning similar work.

The foundation of the Roanoke survey was practically completed in the early part of 1893 when Mr. Wood went to Baltimore where a similar survey was being contemplated. Here he submitted such a comprehensive plan for the undertaking, backed up by the experience and results attained at Roanoke, that he was at once placed in charge of the triangulation, precise traverse work, and property surveys by the chief engineer of The Topographical Survey of Baltimore, Col. H. T. Douglas. After eighteen months Mr. Wood was placed in charge of the entire field work, including street extensions, plans for annexed areas, and map publication. During this time Colonel Douglas submitted to the late Samuel M. Gray,[4] M. Am. Soc. C. E., of Providence, R. I., a notable engineer of his time, some of the maps produced from this survey and received word from Mr. Gray that they were the finest that he had ever seen.

Aside from the precision, thoroughness, and scope of this survey, there was a unique feature that has a distinct bearing upon municipal and state surveys now being undertaken—namely, that it was then thought desirable to tie in the city triangulation to a Coast and Geodetic Secondary, and this was properly done. However, the traverse surveys made with accurately compared tapes within minute limits of error demonstrated that somewhere an error existed, and it became necessary to measure two base lines which were found to be accurate with a minute probable error comparable to the most accurate United States Geodetic Survey work. The Coast Survey Secondary Triangulation to which the Baltimore survey was tied was readjusted accordingly. There was therefore in this survey, in addition to precise triangulation and traverse work, a definite tie-in with the fundamental government triangulation.

---

[3] For memoir, see *Transactions*, Vol. LXXXI, December, 1917, p. 1827.

[4] For memoir, *ibid.*, Vol. LXXXV (1922), p. 1679.

In succeeding years the survey maps, notes, and records have been of continuing value not only in adjusting property boundaries, but in providing an accurate basis for municipal additions and unexcelled maps for drainage and sanitary planning. The entire system was and is expressed by rectangular coordinates centering on the head of the statue on the Washington Monument, center of Baltimore City, and after fifty years the survey is the accepted Baltimore standard.

Work on the Baltimore survey was discontinued in April, 1897, when Mr. Wood entered the service of the District of Columbia in the development of street and sewer additions. In July of the following year he was employed by the Bureau of Yards and Docks of the United States Navy Department as draftsman, where he was rapidly advanced to the position of chief draftsman, serving under the late Admiral Mordecai T. Endicott,[5] Past-President, Am. Soc. C. E., and the late Admiral H. H. Rousseau,[6] M. Am. Soc. C. E., with a distinction that is verified by a correspondence that attests his sound judgment and practical capacity.

In 1906 the late J. Waldo Smith,[7] Hon. M. Am. Soc. C. E., was preparing plans for the first Catskill Aqueduct. Since this project offered a wider scope for his engineering career, Mr. Wood resigned from his position with the Bureau of Yards and Docks and entered the service of the Board of Water Supply of New York, N. Y., remaining with that organization to the completion of the Aqueduct in 1917.

His first assignment was an investigation of the possible use of the Peekskill Creek watershed as a temporary source of water for New York City, and this report still stands as an example of thorough investigation followed by logical and practical deductions. When construction of the Aqueduct began the following year, Mr. Wood was assigned to the Peekskill Division as assistant engineer. Later he was advanced to senior section engineer, and in 1911 he was made division engineer of the Peekskill Division, where he remained to the completion of the enterprise. During this time the contractor on this Division failed, and the sureties for completion then divided the work into four contracts, entailing upon the engineer not only the technical attention required for a large and difficult piece of construction, but also the use of mature judgment and diplomatic handling of the various contracting interests. All of the work was completed successfully. The work on this Division included not only the conventional cut-and-cover construction, but a number of tunnels and steel siphons with the attendant details for handling water transportation.

The Aqueduct finished, Mr. Wood resigned from the service of the Board of Water Supply and for the twelve succeeding years devoted himself to private business, to the development of patents applying to concrete construction, and to agriculture. At the same time he took an active part in the town government of Peekskill, N. Y., where he lived until his death. Good citizenship ranked with good engineering in Mr. Wood's estimation, and his associates still bear witness to this trait of his character.

---

[5] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 91 (1927), p. 1051.

[6] For memoir, *ibid.*, Vol. 95 (1931), p. 1597.

[7] For memoir, *ibid.*, Vol. 101 (1936), p. 1502.

In the year 1929 the town of Peekskill found that its water system needed improvement and employed Mr. Wood to rebuild the pumping plant and extend the distribution facilities. At the expiration of a year he was appointed superintendent of the Peekskill Water Board, serving until his death. During this time he extended the storage and elaborated the filter and treatment systems and so conducted the management of the water property that it became more than self-supporting and is now (1942) rapidly liquidating the obligations incurred by construction and maintenance. At the same time the work of maintenance was so planned that during the "depression" it was made to employ many that otherwise would have been dependent on charity.

Mr. Wood's last work was the extension of the Wickopee watershed and the design and building of the second Wickopee Dam, completed in the summer of 1940. The extension of this water supply was Mr. Wood's own conception and the dam built on his own design now properly bears his name, a memorial from the municipality which he served so faithfully.

In September, 1940, Mr. Wood prepared a paper[8] descriptive of the Peekskill water system, especially related to the Wickopee watershed and the Wickopee Dam. He submitted copies to the Water Board at its regular meeting on the night of October 14, 1940, and on presentation of this last record of his work he was stricken with a cerebral lesion. He was taken home by his associates and passed to his reward on the following day.

Mr. Wood's library bears evidence of unremitting study during his entire career, the record of his work shows sound judgment in the application of his reading and research, his management of every duty assigned to him was admirable, and his character was above reproach. He was considerate in all his dealings. To some he seemed reticent but he had a courage of his convictions that enforced quality and fairness in all he undertook. His seeming diffidence was never due to any lack of confidence in his own conclusions. He wished to look at all matters from all sides; then his decisions stood.

Such is the record of a wise and understanding engineer, an upright public servant, a public-spirited citizen, and an unfailing friend. The following is the characterization of one who was associated with him in his early enterprises: "Personally, I consider George P. Wood as one of the best men I have ever known. He was utterly incapable of any meanness. I am proud to have had his friendship for fifty years."

Mr. Wood was married to Mary Ridout, of Roanoke, on April 12, 1894, and is survived by Mrs. Wood and by two sons, Maj. James Wood, U. S. Marine Corps, and Winchester Wood. A daughter, Mary, died on October 10, 1913.

He was a charter member of the Association of Engineers of Virginia, the University Club of Washington, D. C., and the University Club of Peekskill; and a member of the Thayer Society of Dartmouth College.

Mr. Wood was elected a Member of the American Society of Civil Engineers on June 6, 1911.

---

[8] *Water Works Engineering*, September, 1940.

KENNETH CRAWFORD WRIGHT, M. Am. Soc. C. E.[1]

Died December 21, 1940

Kenneth Crawford Wright was born in Brigham, Utah, on November 11, 1891, the son of Cornelius and Frances (Crawford) Wright, highly respected citizens of northern Utah.

He received his early education in the public schools of his home city, and attended the University of Utah, in Salt Lake City, receiving the degree of Bachelor of Science in Civil Engineering on June 2, 1915. On June 9, 1931, he received the degree of Civil Engineer from the same university.

Mr. Wright was essentially a highway engineer, as nearly all his professional work until March, 1937, was in that field. For the Utah State Road Commission he served as bridge designer, road agent in charge of maintenance, resident engineer on construction on numerous projects, district engineer, assistant chief engineer from April, 1928, finally becoming chief engineer for the Commission on March 1, 1933. He continued in this capacity until March, 1937, when he resigned. He then served as manager of the industrial division of the John Lang Company until his death.

The John Lang Company for a long time has been a leader in its field. It was begun many years ago as a one-man welding enterprise and rapidly expanded to include manufacturing and selling of a very complete line of heavy equipment, the greater part of which is used in heavy engineering construction. This industrial division dealt chiefly with tractors, bulldozers, power shovels, motor graders and carriers, and since Mr. Wright's work of a great many years formed an excellent background for the selection and use of such equipment it was natural that John Lang should engage him for this important post of manager. He filled the position for nearly four years, with credit to himself and satisfaction to his company.

In March, 1935, the Utah legislature enacted the Professional Engineers and Land Surveyors law, patterned closely after the Society's Model Law for the Registration of Professional Engineers and Land Surveyors. Mr. Wright took an active part in advocating this and securing its passage, and in fitting recognition of that he was given license No. 1. He was chairman of the board of seven engineering examiners, provided for in the law, from the time it was formed until his death, and he rendered a real service to the profession in that capacity.

He was a man of real character; he was public spirited, and bore the respect of his fellow engineers, his associates, and citizens generally. His decisions were reached after careful consideration of all pertinent facts; and when so determined he was tenacious of his opinions, but did not hesitate to modify them should that be justified.

Mr. Wright was president of the Utah Section of the Society in 1936 and Secretary of the Western Association of State Highway Officials in 1937.

---

[1] Memoir prepared by R. K. Brown and H. S. Kerr, Members, Am. Soc. C. E.

He was married to Grace McMaster on September 11, 1916. They had four sons—exceptionally fine boys. The two eldest were attending the University of Utah at the time that their father died. Shortly after Mr. Wright's passing, their second son was killed by a snowslide while skiing—another sad bereavement for Mrs. Wright and her three remaining sons.

Mr. Wright was elected an Associate Member of the American Society of Civil Engineers on June 16, 1924, and a Member on January 14, 1929.

CARL LINCOLN BANNISTER, Assoc. M. Am. Soc. C. E.[1]

DIED JANUARY 14, 1940

Carl Lincoln Bannister was born in Bergen, N. Y., on November 23, 1865, the son of Luther and Mary (Kelsey) Bannister. During his early childhood the family moved to Le Roy, N. Y., and Mr. Bannister received his primary education at the neighborhood district school. Later, he attended Le Roy Academy from which he was graduated. He then returned as teacher of the district school he had once attended. During his spare time he worked for some of the neighboring farmers until the fall of 1891, when he entered Union College, at Schenectady, N. Y. He was graduated from Union College in 1895 with the degree of Bachelor of Engineering. After his graduation, he spent the balance of that year in Schenectady, as rodman on city water works construction and as draftsman with the General Electric Company.

On January 13, 1896, he received an appointment as rodman in the New York State Department of State Engineer and Surveyor. This period of service with the state covered about two years, the last year being under the title of leveler.

From September 18, 1898, to July, 1899, Mr. Bannister was employed as draftsman and leveler with the U. S. Deep Waterway Commission. In August, 1899, he entered the employ of the U. S. Engineering Corps, where he remained until June, 1904, when he returned to the New York State Department of State Engineer and Surveyor as assistant engineer. His active work terminated upon his retirement from state service on July 31, 1932. Following his retirement Mr. Bannister resided in Bergen. His death occurred in St. Petersburg, Fla., where he had been spending his winters.

Except for a few months of miscellaneous engineering and short periods of highway surveys and construction, Mr. Bannister's work was centered on waterways. In 1897, he had charge of contracts covering 8 miles of construction for canal improvement for New York State. His work with the Deep Waterway Commission included stadia surveys in the studies of a water supply for a possible ship-canal connection between the Great Lakes and the Atlantic seaboard. Work with the U. S. Corps of Engineers was principally on river and harbor improvement for which he made surveys and inspected construction. His assignments included work on concrete and timber pier construction and dredging at Erie, Pa.; stone breakwater construction at Buffalo, N. Y.; surveys of harbors on Lake Ontario; and river and harbor improvements at Savannah, Ga.

---

[1] Memoir prepared by Leroy C. Hulburd, Assistant Commissioner of Canals of New York State, Albany, N. Y.

In 1904 the New York State Engineer and Surveyor was building an organization for the improvement of the State Canal System, which improvement had been authorized in the previous year. This was one of the major waterway projects undertaken to that time, and many engineers were attracted to the work. Mr. Bannister's ability was recognized from his previous work with the State Engineer and Surveyor, and he was immediately assigned to make preliminary surveys and estimates and to prepare plans for the project. One of his assignments was a survey and report on a proposed extension of the project to include the Chemung (N. Y.) Canal. Although Mr. Bannister conducted surveys and supervised some of the construction on the Improved Canal System, his work was confined principally to office supervision over the preparation of plans and estimates. When that work was brought to a close, his assignment was transferred to the Division of Highways. His employment in that division continued until he retired.

The integrity and loyalty of Mr. Bannister were recognized by all of his associates. His interest in the successful completion of any work under his supervision overshadowed any personal considerations or desires, and the faithful administration of each duty assigned to him contributed to efficient, honest public work.

Mr. Bannister never married. He is survived by two sisters, Cordelia Grace (Mrs. Almer C. Seward), and Mary Charlotte (Mrs. Shelton E. Crittenden).

Mr. Bannister was elected an Associate Member of the American Society of Civil Engineers on May 3, 1905.

EDWARD MORRIS BASSETT, Assoc. M. Am. Soc. C. E.[1]

Died August 2, 1941

Edward Morris Bassett was born in Salem, N. J., on March 13, 1883, the son of Edward Hicks Bassett and Emma (Hall) Bassett. He prepared for college at the public high school in Salem and the Swarthmore Preparatory School, entering Swarthmore College, at Swarthmore, Pa., in the fall of 1900. He left college after his sophomore year to spend the year 1902–1903 with the United Gas Improvement Company as sheet clerk in the Department of Records, where his work consisted largely of surveying and recording changes in the street mains. In March, 1903, he went to Gary, W. Va., as rodman for the United States Coal and Coke Company, working on topographical surveys, layout, and inspection of the construction of coke ovens.

---

[1] Memoir prepared by Scott B. Lilly, M. Am. Soc. C. E.

In the fall of 1903 he returned to Swarthmore College, receiving his degree of Bachelor of Science in Engineering with the class of 1905. He showed his versatility by becoming editor of the *Phoenix*, the college newspaper, at that time a monthly; leader of the mandolin club; and member of the football team, a most unusual combination for an engineer. He received the degree of Civil Engineer from Swarthmore College in 1911.

His first job after graduation was with the Pennsylvania Railroad Company. He stayed with it for only one year, during which time he worked upon changes in line in connection with the Union Station then being built in Washington, D. C. He resigned from the Pennsylvania Railroad Company in 1906 to take a position with Ransome and Smith Company, General Contractors, in New York, N. Y., and began his career in building construction. This company had many contracts for concrete buildings in New York State and Connecticut.

He returned to Philadelphia, Pa., in 1907 to become engineer of construction with Doyle and Doak, later Doyle and Company. He remained with this company until 1916, during which time it built the Bulletin Building, the Curtis Building, the Penn Mutual Building, the Hotel Vendig, and many other important structures in downtown Philadelphia.

From 1916 to 1918 he was with Warren, Moore and Company, again on building construction, the most notable contracts being with the United States Government for the foundry building at League Island, Pa., the projectile plant at Charleston, W. Va., and structures in the Washington (D. C.) Navy Yard.

From 1918 until his death he was vice-president and general superintendent of Wark and Company. With this company he continued to build notable buildings in Philadelphia and elsewhere. The following list is chosen to show the different types of construction in which Wark and Company engaged, all of the buildings being in Philadelphia: Babies Hospital, 7th and Delancey streets; Dispensary Building, Presbyterian Hospital; 18-story Samuel Gustine Thompson Annex, Jefferson Hospital; Western Union office, 11th and Locust streets; office buildings at 1600 Walnut Street, 1608–14 Walnut Street, and 1916–22 Walnut Street; and Architects Building, 17th and Sansom streets. Outside of Philadelphia the company built large manufacturing buildings for E. G. Budd and Company and the Viscose Company, and many large structures for the United States Government. Readers who are familiar with Philadelphia will realize what a large part Mr. Bassett had in changing the sky line of that city.

During the time that Mr. Bassett was general superintendent, Wark and Company used plywood for concrete formwork in the construction of the United States Marine Corps Building, 15th and Washington Avenue, Philadelphia. It is believed that this is the first time that it was used for this purpose in the Philadelphia area. Wark and Company were also pioneers in using adjustable shores for reinforced-concrete building construction. These were used for the first time in the Philadelphia area in connection with the Gulf Oil Company office building in 1924.

Mr. Bassett's success was due not only to his engineering knowledge but also in a marked degree to his ability to encourage men to work together. From his early days with Doyle and Doak, when he was charged with seeing that each subcontractor maintained his schedule, until the time of his death, when he had under his supervision construction worth millions of dollars, Mr. Bassett succeeded in getting a close coordination among all the firms and individuals involved. This resulted in buildings being built quickly and well.

This ability to lead men is shown throughout Mr. Bassett's career. In college he was a member of Phi Kappa Psi fraternity. In later life he was elected treasurer of the national Phi Kappa Psi in 1926, again in 1928, and later was president of this fraternity. He was a member of Swarthmore Borough Council and later Burgess. He was president of the Swarthmore Building Association, and for many years was a member of the Board of Managers of Swarthmore College. All of these items testify to the regard and confidence of his associates. The pleasure that Mr. Bassett derived from association with his fellowmen is shown by the fact that he was a member of the Union League of Philadelphia, the Penn Athletic Club, and the Rolling Green Golf Club.

Mr. Bassett is survived by his widow, Ellie Simons Bassett, and his children: Kathryn, Elizabeth, and E. Morris, Jr.

Mr. Bassett was elected an Associate Member of the American Society of Civil Engineers on March 14, 1916.

ADAM CARL BEYER, Assoc. M. Am. Soc. C. E.[1]

DIED APRIL 30, 1941

Adam Carl Beyer was born in St. Paul, Minn., on June 20, 1901, the son of Adam Carl Beyer and Mina (Butler) Beyer. His father died before he was born. At an early age he moved to California with his mother and completed his education at the University of California, in Berkeley, from which he was graduated in 1925 with the degree of Bachelor of Science in Civil Engineering. He was an outstanding student leader in college, was elected to many honor societies (including Phi Beta Kappa, Tau Beta Pi, and Sigma Xi), and was president of the student body.

Following his graduation, he accepted several professional engagements with the California Highway Commission, the Southern Pacific Railroad Company for the City of San Rafael, Calif., and the Pelton Water Wheel Company. In February, 1929, he entered the employ of the Wallace and Tiernan Company in San Francisco, Calif., as sanitary engineer and district manager. He remained in the employ of this company until his death. He was a specialist in the field of sanitary engineering equipment, designing and constructing many important installations throughout the West.

---

[1] Memoir prepared by Gerald E. Arnold, M. Am. Soc. C. E.

Mr. Beyer was a member of numerous technical and professional societies and served as an officer in most of them. He was the representative of the San Francisco Section of the Society on the San Francisco Engineering Council. He was a director of the San Francisco Junior Chamber of Commerce.

In May, 1932, he was married to Mary Katherine Barry. He is survived by his widow and by two children—a daughter, Mary Ellen, and a son, Barry Michael.

His was an outstanding life of service and fellowship to his friends and associates. He was known by many, and all who knew him loved him.

Mr. Beyer was elected a Junior of the American Society of Civil Engineers on December 14, 1925, and an Associate Member on February 24, 1931.

JOHN CANTLEY, Assoc. M. Am. Soc. C. E.[1]

DIED JANUARY 11, 1941

John Cantley was born in Nicetown, Philadelphia, Pa., on December 9, 1874, the son of Andrew and Mary Ann (Beatty) Cantley.

As a boy he attended the public schools of Philadelphia in the vicinity of East Falls, later enrolling in the mechanical engineering course in the evening school of Temple University, in Philadelphia.

In December, 1891, at the age of sixteen, he entered the service of the Pencoyd Iron Works (later merged with the American Bridge Company) as a structural draftsman. While in the employ of the Pencoyd Iron Works, he furthered his engineering education by diligently attending a special training course which the company offered to the ambitious young men in its employ.

By 1903, Mr. Cantley had gained sufficient recognition to be placed in charge of a squad of engineers and draftsmen engaged in the detailing of numerous buildings, such as the New York, N. Y., and Philadelphia stores of John Wanamaker, and the Hudson Terminal and Pennsylvania Railroad Station in New York.

In 1901, Mr. Cantley, having been granted a short leave of absence, assisted Sax and Abbott, Consulting Engineers of Philadelphia, in the preparation of plans and details for the Pennsylvania Arcade and Union League Buildings in Philadelphia. Again in 1905, on a short leave of absence, he assisted the American Bridge Company office in the design in the Sonneborn Building, Baltimore, Md.—a structure of steel and concrete.

In 1909, Mr. Cantley became associated with Steel and White Company, Iron Works, in full charge of all engineering work on many well-known department stores, churches, and hospitals in the vicinity of Philadelphia.

---

[1] Memoir prepared by Samuel Bernhang, Assoc. M. Am. Soc. C. E.

In April, 1913, Mr. Cantley entered the service of the City of Philadelphia as an engineer in the Bureau of Building Inspection. His work included the examination of plans for all types of buildings and structures.

Mr. Cantley was known throughout Philadelphia as the outstanding designer of structural steel and as an expert on theater design, being of great assistance to numerous architects with advice and suggestions.

On October 6, 1895, he was married to Mary Jane Clayton. He is survived by his widow and three children, Walter John, Herbert Watson, and Mrs. J. Franklin Wooler. He was a devoted husband and father and to his many friends and admirers his sincerity and kindness were a constant source of encouragement.

Deeply interested in his profession, he was always ready with advice and encouragement to help the young architect and engineer along the path of the profession.

Mr. Cantley was elected an Associate Member of the American Society of Civil Engineers on March 14, 1916.

HARTLEY ROBERT CHURCH, Assoc. M. Am. Soc. C. E.[1]

DIED APRIL 21, 1941

Hartley Robert Church was born in Remington, Ind., on November 13, 1876, the son of Osman W. and Emroy Jane (Lyon) Church. He was graduated from Earlham College at Richmond, Ind., in 1896 with the degree of Bachelor of Science.

From 1901 to 1905 he served with the Western Division of the Atchison, Topeka and Santa Fe Railway Company in various capacities from chainman to assistant engineer.

For the next seventeen years he was connected with various private engineering and construction firms engaged in the design and construction of sewage systems and sewage disposal works, irrigation systems, city paving, etc. During this period he was connected with the following organizations in California: Stephen E. Kieffer, M. Am. Soc. C. E., Berkeley; Haviland and Tibbetts, San Francisco; Church and Beugler, Oakland; the late Philip Schuyler,[2] M. Am. Soc. C. E., Oakland; City of Berkeley; Interstate Commerce Commission; Fair Oaks Irrigation District; Southern Pacific Railroad Company; and the Cosumnes Irrigation District.

He entered the service of the California Division of Highways in February, 1922, and remained in this service until his death, advancing from the junior engineer grade to that of associate highway engineer with the San Luis Obispo District Office.

Mr. Church was a member of King David Lodge No. 236, F. and A. M., of San Luis Obispo. He was extremely active in the church, and was an ardent worker in the Boy Scouts and other worthy local civic activities. His lovable character endeared him to all with whom he came in contact.

---

[1] Memoir prepared by T. E. Stanton, M. Am. Soc. C. E.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 96 (1932), p. 1547.

On November 20, 1902, he was married to Katharine Parker, who, with two sons, Osman and Robert, survives him.

Mr. Church was elected an Associate Member of the American Society of Civil Engineers on June 6, 1911.

JAMES SINGLETON CLAY, Assoc. M. Am. Soc. C. E.[1]

DIED JANUARY 2, 1942

James Singleton Clay was born in Germantown, Philadelphia, Pa., on April 10, 1889, the son of George and Mary (Musgrove) Clay. He attended the University of Pennsylvania in West Philadelphia and was graduated in 1912 with the degree of Bachelor of Science in Civil Engineering. In 1917 he received the degree of Civil Engineer.

After graduation Mr. Clay was employed as bridge designer with the Department of Public Works of the City of Philadelphia, where he remained from June, 1912, to March, 1917.

On March 16, 1917, he entered the service of the federal government as highway bridge engineer for the Bureau of Public Roads (later the Public Roads Administration) in Washington, D. C. He served two assignments as bridge engineer in two of the District offices as follows: From September, 1920, to December, 1927, at Montgomery, Ala., and from December, 1927, to April, 1930, at Troy, N. Y. From April, 1930, to the time of his death, he served as senior highway bridge engineer in the Washington, D. C., office as first assistant to the principal bridge engineer.

Mr. Clay was a man of unusual thoroughness and was a lover of nature, music, and literature. He had a keen insight into engineering problems and was an accurate analyst and logician. His associates found him to be a man of retiring disposition—quiet, unassuming, and independent in thought and action. He was never given to boasting or self-aggrandizement and, although he naturally shouldered responsibility, he continually won the respect and friendship of his associates.

Mr. Clay was never married. He devoted his life to his family. He is survived by his sister, Mary.

He was an associate member of the Society of American Military Engineers.

Mr. Clay was elected an Associate Member of the American Society of Civil Engineers on May 12, 1919.

---

[1] Memoir prepared by Nathan Wilson Morgan, M. Am. Soc. C. E.

ROBERT HARE POWEL CORLEY, Assoc. M. Am. Soc. C. E.[1]

Died December 8, 1941

Robert Hare Powel Corley, the son of Peter A. and Lilly (Lees) Corley, was born on October 19, 1885, at Saxton, Bedford County, Pa. The family moved to Philadelphia, Pa., establishing a residence in Roxborough. Mr. Corley was educated in the Philadelphia public schools and was graduated from Central High School in June, 1904, with the degree of Bachelor of Science.

He began his engineering work with the Pencoyd Iron Works Division of the American Bridge Company, where he completed a term of apprenticeship in structural design on May 31, 1907. The following spring he was transferred to the American Bridge Company plant at Ambridge, Pa. In 1909 he accepted a position as assistant engineer with the Milliken Company in Staten Island, N. Y., which position he held until the failure of the firm in 1910.

From 1911 until 1918 he held responsible engineering positions with the Hay Foundry Company and the Interboro Rapid Transit Company of New York, N. Y., and the Midvale Steel Company of Philadelphia. While with the Interboro Rapid Transit Company his entire time was occupied on design for reinforcing the various elevated structures operated and controlled by this company. His special assignment was the design of the added overhead structure for third-track express operation during morning and evening peak loads.

In 1920 Mr. Corley accepted the position of structural designer with the Philadelphia Rapid Transit Company and remained in the employ of this organization and its successor, the Philadelphia Transportation Company, until his death on December 8, 1941. During the twenty-two years that he was connected with the Philadelphia Transportation System, his engineering ability, resourcefulness, and untiring energy were recognized by his superiors. Several times he was advanced to positions of higher authority, culminating in that of engineer of designs. In this position he was responsible for all structural and building design and construction for the entire system.

Quiet and unassuming in manner, and highly conscientious, Mr. Corley possessed a sense of honor and understanding that will long be remembered by his friends and associates. The men who worked for and with him loved him and swore by him. He was absolutely reliable in everything he said and did, true and devoted to his family, his friends, his masonic lodge, and his church, as well as to the engineering profession and the Society of which he was so proud. He was an active member of St. Timothy's Episcopal Church in Roxborough, and a member of the Masonic Fraternity, Lafayette Lodge No. 27, located in Rahway, N. J.

In October, 1910, Mr. Corley was married to Elizabeth Bottomley of Roxborough. He is survived by his widow; by four children, Robert, Jr., Ruth,

---

[1] Memoir prepared by L. F. Parlette, M. Am. Soc. C. E.

Edith, and Helen; by four brothers, James, Thomas, Paul, and William; and by two sisters, Mary Braddock and Margaret Hertica.

Mr. Corley was elected an Associate Member of the American Society of Civil Engineers on July 6, 1936.

GEORGE WARREN CUTTING, JR., Assoc. M. Am. Soc. C. E.[1]

Died February 4, 1942

George Warren Cutting, Jr., the son of George Warren Cutting and Josephine (Brown) Cutting, was born in Weston, Mass., on October 12, 1877, of New England Puritan stock. From the Weston public schools he went to the Massachusetts Institute of Technology, at Boston, Mass., where he was a member of the Class of 1900. His engineering career began in his summer vacations when he acted as rodman for the city engineer of Newton, Mass. After three summers and one winter in the latter position, he served for a year as rodman and acting transitman with the Massachusetts Highway Commission.

Between 1900 and 1905, the Metropolitan Water Works was extending the water supply of the City of Boston by building the Wachusett Reservoir at Clinton, Mass., and the Weston Aqueduct, with a smaller aeration reservoir in Weston. At first Mr. Cutting was recorder on construction at Clinton. Later, at Weston, he was advanced from rodman to engineer and for two years was in charge of the Division office work.

After the completion of this Metropolitan system, Mr. Cutting took a position with the National Board of Fire Underwriters, Committee of Twenty, in New York, N. Y., for whom he examined and reported upon water-works systems and fire departments of various cities, mostly in the South. He returned to Massachusetts and spent a year with the Massachusetts State Board of Health as assistant on sanitary and hydrographic investigations.

In 1906 he opened a private office in Waltham, Mass., where he engaged in general engineering practice, surveys, road and masonry construction, drainage, grading, abolition of grade crossings, etc. In 1910 he received an appointment in the Quartermaster Department of the United States Army, and for a year he was engineer with the Constructing Quartermaster at Fort Mills, Corregidor Island, in the Philippines. This work was particularly interesting. He went to Corregidor by way of the Pacific Ocean, and returned to the United States via Asia, Africa, and Europe.

Upon his return, he opened a private office in Boston, instead of in Waltham. This he maintained from 1911 to 1941. During the first World War, he served as engineer for Stone and Webster on the housing project connected with the Atlantic Ship Building Corporation at Portsmouth, N. H. When the houses were completed, he went into the Engineering Department of the Atlantic Ship Building Corporation, where he remained until 1920. When he returned to

---

[1] Memoir prepared by Helen E. Cutting, Weston, Mass.

Boston, he did a great deal of local work in Weston, Wayland, and Lincoln, Mass. For two years he was with the Metropolitan Planning Board, at the time when it was laying out the Northern Artery and the Gallivan Boulevard.

Throughout his life, Mr. Cutting was interested in military affairs. His early training was at Massachusetts Institute of Technology. For some years he was in the Massachusetts State Guard, a member of the First Squadron Cavalry, and a National Lancer. Later he was in the 94th Division, 319th Engineers, U. S. Army. His commission as Captain was in Washington, D. C., awaiting signature when the Armistice was signed in November, 1918, but after the war he remained a member of the Engineer Reserves. When a physical condition prevented his remaining with the Engineers, he was transferred to the Quartermaster Department and commissioned a Major.

The Cutting family in Weston always gave devoted service in public office. Mr. Cutting's father was Town Clerk of Weston for fifty-two years, and his brother, Alfred L. Cutting, was a member of the Board of Selectmen for twenty-five years; so it was natural enough for George Cutting to take on the duties of Treasurer and Collector, an office which he held for nearly twenty-one years.

With deep devotion to his church and to the principles of a true Christian, he brought to his work and to his relationships with the townfolk such faithfulness, such keen interest, and such kindliness that he won the love and respect of all.

In 1912 he was married to Helen Ellms Warren. He is survived by his widow, by one daughter, Mary, and by two sisters, Sarah L. (Mrs. Arthur B. Nims), and Eleanor M.

Mr. Cutting was elected an Associate Member of the American Society of Civil Engineers on May 3, 1910.

HARRY JOHNSON DEUTSCHBEIN, Assoc. M. Am. Soc. C. E.[1]

Died February 8, 1942

Harry Johnson Deutschbein was born in Canaan, N. Y., on August 13, 1880, the son of Joseph E. Deutschbein and Eliza (Johnson) Deutschbein. His father came to the United States, at the age of eighteen, from Southern Germany soon after the revolutionary disturbances of 1848. His mother was descended from a family that had been settled in and near Canaan since the time of the American War of Independence.

After their marriage, his parents settled in Albany, N. Y., where young Deutschbein spent his early life. He received his education from the public schools there until his graduation from the Albany High School in 1898. Although a few months under the age limit, he enlisted in the 1st New York Volunteers, then being recruited for service in the Spanish-American War.

---

[1] Memoir prepared by Francis S. Crowell, M. Am. Soc. C. E.

After several months of training, he accompanied his regiment to the Pacific Coast, where it was embarked for duty in the Philippine Islands. However, the termination of the war caused the detention of the expedition in Hawaii, where the soldiers were encamped until early in 1899, when they were returned to the United States and the regiment was disbanded.

In the autumn of 1899 Mr. Deutschbein enrolled in the freshman class of Rensselaer Polytechnic Institute at Troy, N. Y. He was graduated four years later with the degree of Civil Engineer. During the intervening summers he held several positions as transitman and inspector on survey and construction work in and near Albany. After graduation he went to work in the office of the chief engineer of the Duluth and Iron Range Railroad Company in Minnesota, where his duties were of a general nature, involving projects of survey, maintenance, and new construction. After a year, however, he returned to the East to enter the employ of The Foundation Company, with which he was later to be so intimately associated, but after a short period of work in New York, N. Y., he was induced to return to Albany, where in October, 1904, he was appointed deputy city engineer. In this position, which he held for the succeeding three or four years, he directed the program of modernization of the paving and sewerage of the growing city. In 1908 he was transferred from the Bureau of Engineering to the Bureau of Water Supply as superintendent of water works. His duties in the latter position included the construction and later the operation of the new slow-sand filters, as well as the reconstruction of the pumping and distribution facilities throughout the city and its environs. This work resulted in the practical obliteration of typhoid fever in Albany.

In 1912 Mr. Deutschbein returned to The Foundation Company, this time to continue with it for almost twenty years. After serving as construction engineer and superintendent on several large projects on the Ohio River and the New York Barge Canal, he was recalled to the head office of the company in New York City as district manager. Two years later, in 1917, he became vice-president and general manager. From this time onward he was in direct charge of all the company's work in the United States, Mexico, and South America. After 1926, when he was advanced to president, through affiliated companies, he had charge of all the company's work in Europe as well. It was during these years that the company was built up to the dominating position which it occupied in its field during the 1920's and early 1930's, especially in the construction of deep piers and caissons by the pneumatic method.

In 1929 Mr. Deutschbein withdrew from The Foundation Company to form the company which bears his name. He served as its president until his death. Under his direction this company has completed a large number of important construction projects in the field of deep foundations and heavy engineering work, and has been engaged in construction work of magnitude for the United States Government.

Mr. Deutschbein was a member of the American Concrete Institute; the Chi Phi fraternity; the Sigma Xi honorary society; and the Engineers', Downtown Athletic, and Rockefeller Center Luncheon clubs of New York City. He served on the Joint Committee on Masonry Dams of the Society, and on the Sectional Committee of the American Standards Association on Building Code Requirements for Excavation and Foundations. For the latter Committee he was chairman of the Subcommittee on Caissons and Cylinders.

Mr. Deutschbein was known to a large circle of clients, associates, and friends as an engineer of more than usual ability. He was widely recognized as an authority on all questions appertaining to construction work and methods, especially those in the field of deep and difficult foundations involving subterranean and subaqueous problems. His advice on these questions was eagerly sought and widely adopted. His untiring industry, a direct and forceful personality, a highly trained and logical power of reasoning, and a lovable personal charm explain his success and the friendships that he formed wherever he went. He was an intensely active man to whom death came too soon. His departure leaves a gap which is keenly felt by many.

In 1905 Mr. Deutschbein was married to Frances Ethel Dresser, who, with their two children, Harry D. and Ethel H. (Mrs. F. Ashton Smith), survives him.

Mr. Deutschbein was elected a Junior of the American Society of Civil Engineers on December 6, 1904, and an Associate Member on January 7, 1913.

SAMUEL DOUGLASS DODGE, Assoc. M. Am. Soc. C. E.[1]

Died December 11, 1941

Samuel Douglass Dodge was born on November 29, 1870, in Grinnell, Iowa, and died at his home in Suffern, N. Y., on December 11, 1941. He was the son of Joshua G. and Mary F. (Herrick) Dodge, a descendant of an old New England family.[2]

Samuel Dodge possessed a scholarly mind. He was graduated from the Massachusetts Institute of Technology at Boston, Mass., with the degree of Bachelor of Science in Civil Engineering in 1893. His high standing in mathematics, applied mechanics, etc., resulted in an invitation to return to the Institute after graduation as an instructor in the theory of structures. He accepted, and remained at the Institute for about one year.

For the next year and a half he was instrumentman with the Water Board of Winchester, Mass. From 1895 to 1905 he was in the employ of the Metropolitan Water Board of Boston on the location and construction of pipe lines, reservoirs, masonry water towers, subaqueous tunnels, etc.

The ten years from 1906 to 1916 were spent with the Board of Water Supply of New York, N. Y. As section engineer he located several miles of the Catskill Aqueduct just west of the Hudson River and was in charge of construction of three deep shafts and about three miles of tunnel on the Moodna siphon of the Aqueduct. At the latter end of this period he was engaged on statistical and literary work in connection with a history of the work of the Board of Water Supply of New York City.

---

[1] Memoir prepared by William E. Swift, M. Am. Soc. C. E.

[2] *Who's Who in Engineering*, 1925, p. 568.

During World War I he was supervising and production engineer in the Ordnance Department of the United States Army. First he supervised the construction of a water supply system for an extensive smokeless powder plant at Nitro, W. Va. Later, he was connected with the production of picric acid in the New York Ordnance District. Mr. Dodge became interested in the Richmond Screw Anchor Company and after the war accepted the position of treasurer of this company. He resigned about five years before his death.

Samuel Dodge was a gentleman in the truest sense. He was interested in music, art, and drama, and was well informed on topics of the day. He maintained a live interest in civic affairs. In 1917 he purchased a large apple orchard near Suffern. He built a comfortable house among the apple trees in 1918, and this was his permanent residence until his death. Because of his unselfishness, absolute straightforwardness, and keen sense of humor, his home life was ideal. He was to be depended upon as a friend.

On June 12, 1913, he was married to Margaret Stone of Cornwall, N. Y., who, with two sons, David and Eric Douglass, survives him.

Mr. Dodge was elected an Associate Member of the American Society of Civil Engineers on November 6, 1907.

WALTER THOMAS EVANS, Assoc. M. Am. Soc. C. E.[1]

DIED AUGUST 9, 1941

Walter Thomas Evans was born at Wales, Wis., on December 2, 1887, the son of David Richard Evans and Sarah (Price) Evans. His grammar school and high school days were spent in Racine, Wis. He entered Illinois Wesleyan University, at Bloomington, Ill., in 1907, and at the end of his freshman year transferred to the University of Illinois, at Urbana, where he pursued a course in railroad engineering and administration for two years.

In June, 1910, he entered the employ of the Chicago and Alton Railroad Company in its engineering department. He served as rodman and instrumentman from June, 1910, to January, 1914. From January, 1914, to January, 1916, he served as assistant engineer on maintenance and construction at Bloomington. He served as chief draftsman from January, 1916, to 1923, with headquarters in Chicago, Ill., and during this time he had charge of mapping the entire Chicago and Alton Railroad system. He was in charge of making valuation maps for the entire road and of compiling Valuation Order No. 7, which consisted of looking up and listing all the title instruments for each individual parcel of land belonging to, or used by, the railroad. He also acted as pilot engineer for the Interstate Commerce Commission parties on federal valuation. He assisted in the design of yards and terminals.

---

[1] Memoir prepared by Alfred Jones, Assoc. M. Am. Soc. C. E., and Gifford G. Todd, Chf. Valuation Engr., Office of County Surv. and County Engr., County of Los Angeles, Los Angeles, Calif.

In the latter part of 1923 Mr. Evans severed his connection with the Chicago and Alton Railroad Company and moved to California. From January, 1924, until the spring of 1927 he served as secretary and plant superintendent of the California Crushed Fruit Corporation at Los Angeles, Calif. In this connection he equipped the plant and had charge of the installation of the machinery. This concern shipped their products to all parts of the United States and foreign countries.

In the spring of 1927 he entered the employ of the Los Angeles County surveyor's office, still retaining a financial interest in the Crushed Fruit Corporation. Soon after entering the county surveyor's office, he was selected for valuation work in connection with highways and other governmental matters. He served as a valuation engineer until his death.

Mr. Evans was a member of the Phi Kappa Sigma Fraternity, a registered civil engineer of the State of California, a charter member of the American Right of Way Association, and a member of Crescenta Valley Lodge No. 652, F. and A. M. in Montrose, Calif.

At the time of his death he was residing in Glendale, Calif. He is survived by his widow, Jessie J. Evans, to whom he was married on May 14, 1913, and a daughter, Gloria Irene Evans.

A conscientious and kindly individual, and an inspiring worker, he will long be remembered, as a real friend, by those who had the pleasure of working with him.

Mr. Evans was elected an Associate Member of the American Society of Civil Engineers on March 5, 1928.

WARREN GLENN FOWLER, Assoc. M. Am. Soc. C. E.[1]

Died February 14, 1941

Warren Glenn Fowler was born on December 15, 1895, in Vandalia, Mo., the son of James W. and Mary Susan Fowler. He was educated at the University of Missouri at Columbia, Mo., and was graduated in 1919 with the degree of Bachelor of Science in Engineering. In 1919–1920 he took postgraduate work at the University of Missouri. As research assistant at the Engineering Experiment Station, he collaborated in the preparation of a bulletin, "Study Relating to the Water Resources of Missouri." He was granted the degree of Civil Engineer in June, 1920, at the conclusion of this work. He was awarded the "Gregory Senior Scholarship" in 1919 and was a member of Tau Beta Pi.

In the summer of 1918 he was engaged on drainage work in the St. Francis River lowlands in southeastern Missouri, and in the summer of 1919 served as a transitman, maintenance of way, with the St. Louis-San Francisco Railway Company in Springfield, Mo.

---

[1] Memoir prepared by Charles A. Haskins, M. Am. Soc. C. E.

For three years after the completion of his school work he was structural and mechanical designer with Heyl and Patterson, Inc., of Pittsburgh, Pa., engaged in design and estimating on conveying machinery, coal and coke plants, etc. In May, 1923, Mr. Fowler was employed by the Bureau of Bridges, Missouri State Highway Commission, as special designer. During this period he was engaged on the design of three bridges across the Missouri River. In May, 1924, he was promoted to chief draftsman and from then until August, 1926, was in charge of the drafting room on bridge plans and standards for more than four hundred bridges, including fourteen concrete arches and a large steel cantilever.

In August, 1926, he was appointed bridge engineer, Board of Park Commissioners, at St. Joseph, Mo., and was in charge of the preliminary study, design, and erection of ten bridges for the extensive boulevard and parkway project in that city. From 1927 to the time of his death Mr. Fowler was office engineer for the firm of Black and Veatch, Consulting Engineers, of Kansas City, Mo., and was in responsible charge of a large number of engineering projects of great variety.

Mr. Fowler took an active interest in the affairs of the Society, and he served the Kansas City Section faithfully and well. He was elected secretary-treasurer in 1940 and vice-president in 1941, which office he held at the time of his death. His friendly but quiet personality and his efficiency in handling the affairs of the Local Section endeared him to all with whom he came in contact.

In 1924 he was married to Dorothy Brittingham of Jefferson City, Mo., who survives him.

Mr. Fowler was elected a Junior of the American Society of Civil Engineers on December 4, 1922, and an Associate Member on March 14, 1927.

RAY STUART GATENS, Assoc. M. Am. Soc. C. E.[1]

Died April 10, 1941

To Patrick Gatens, of Donegal County, Ireland, and Hanna (Cunningham) Gatens, his wife, a native of Quebec, Canada, was born Ray Stuart Gatens on April 29, 1886, at Memphis, Tenn. Ray Gatens' father was a pioneer cotton merchant, an active and honorary member of the Memphis Cotton Exchange, and held a seat on the New York Cotton Exchange. Ray was educated at Christian Brothers College in Memphis and at Notre Dame and Purdue universities, in Notre Dame and Lafayette, Ind., respectively.

Returning to Memphis in June, 1904, he began a career of varied and interesting engineering activities as an inspector on levee construction with

---

[1] Memoir prepared by J. C. Carpenter, M. Am. Soc. C. E.

Le Vasseur and De Beughem, Consulting Engineers, 2d Mississippi River District, U. S. Engineers. During his service he was assigned the supervision of an important part of the work that seemed too difficult for his experience. He asked his father's advice, and Patrick Gatens was concerned for fear that the responsibility might result in a failure that would discourage his son. Mr. Gatens, Sr., consulted an old friend who had had construction experience and his advice was "Let the boy decide for himself. Of course he can handle it, and, if he's 'stuck' I'm here to see him through." The boy decided to take the risk, handled it successfully, and was promoted to resident engineer.

On completion of his first assignment Mr. Gatens was employed for a year in Chicago, Ill., as a city inspector on heavy tunnel construction. For the next six years, 1907 to 1913, he was contractors' engineer for the Parker-Washington Company of St. Louis, Mo., in executive charge of construction; plant layout; and financing and construction design of paving, sewers, water works, and tunnels in Chicago, St. Louis, Kansas City (Mo.), and Oklahoma, involving several million dollars' worth of work.

During 1914 Mr. Gatens engaged in general engineering and surveying at Greenville, Miss., in private practice. As general superintendent and construction engineer for the Continental Public Works Company, of New York, N. Y., in 1915 and 1916, Mr. Gatens was directly or indirectly in charge of a large volume of construction of street paving, highways, sewers, and sewage disposal.

Volunteering for service in the United States Army at the beginning of its participation in the first World War, he was commissioned a First Lieutenant on February 26, 1918, and assigned to the 42d Engineers at American University in Washington, D. C. On completion of the training course he sailed for France on April 11, 1918, on the *President Lincoln.* Immediately on his arrival, April 24, he was placed in command of a company of the 20th Engineers and served throughout the remainder of the war. He was promoted to Captain on May 6, 1919. He returned to the United States on the *Zeelanda* and was honorably discharged at Camp Pike, in Arkansas, on June 21, 1919.

From August, 1920, to October, 1921, Mr. Gatens was general superintendent of construction for the Liberty Contracting Company of New York City on the installation of 18 miles of 72-in. steel pipe line as a part of the water supply for Jersey City, N. J. During the next three years he served as general superintendent for the William P. McDonald Construction Company of New York City in general charge of estimating and construction of street paving, roads, bridges, and sewers in New Jersey, New York, and Florida.

Mr. Gatens was city engineer and city manager of Winter Haven, Fla., in executive charge of all municipal departments from December, 1924, to June, 1928. He was seriously ill and obliged to suspend all professional activities from June, 1928, to the end of 1929.

On his return to practice he again joined the William P. McDonald Construction Company as assistant to the general superintendent and in charge of cost control on projects in New York State and in Creek de Prairie, Quebec, covering construction of street paving, roads, and sewers.

Mr. Gatens was again forced to retire from active practice after a year with the William P. McDonald Company and returned to Florida. He conducted a private engineering practice in Winter Haven and Lakeland in 1932 and 1933.

On October 24, 1933, he was appointed an associate highway engineer in the United States Bureau of Public Roads. His first assignment was on a special force account project in Texas, where he demonstrated a broad-visioned ability beyond the stipulated requirements. He was then placed in charge of cost studies and landscaping projects for the district which includes Arkansas, Louisiana, Oklahoma, and Texas. In August, 1935, he was appointed maintenance engineer for the district, in which position he served until his death. His tact and analytical ability, reinforced with his wide experience in important engineering projects and coupled with a pleasing personality, marked by good humor, served to establish such satisfactory relations with the maintenance organizations throughout the district as undoubtedly resulted in marked improvement in maintenance practice in this area.

During the last two years of his life Mr. Gatens was forced to suspend his field operations several times due to severe illness. He always returned to the field with dogged determination, even when he had not fully recovered. In spite of these handicaps he maintained a cheerful and good-natured mien and few of his business associates realized that he was not in the best of health. He had a magnetic personality and was admired and respected by his many friends.

On February 1, 1913, he was married to Fannie Pringle Cherry, a descendant of the old families of Cherry and Pringle of Charleston, S. C., and a granddaughter of a South Carolina governor. In addition to his widow he is survived by three sisters, Mrs. C. K. H. Byrne and Ann and Agnes Gatens; and two brothers, Thomas J. and James T. Gatens.

Mr. Gatens' college fraternity was Kappa Alpha, and he was a member of the Winter Haven post of the American Legion.

Mr. Gatens was elected an Associate Member of the American Society of Civil Engineers on November 27, 1917.

PHILIP HOLDEN GLOVER, Assoc. M. Am. Soc. C. E.[1]

DIED MAY 30, 1941

The death of Philip Holden Glover brought to a close an unusually interesting and diversified engineering career. Although in poor health for several years, Mr. Glover performed his duties as city engineer of Bangor, Me., cheerfully and efficiently, resigning only a few weeks before his death.

Philip Holden Glover was born in Portland, Me., on February 23, 1883, the son of Capt. Russell Glover and Elizabeth (Nash) Glover. (He was a direct descendant of Dr. Phineas Holdon, who was a surgeon attending the wounded of the battle of Bunker Hill. At the time of Mr. Glover's death, he was in possession of the medicine case used by Dr. Holdon during that battle.) He received his early education in the schools of that city, and then entered the University of Maine, at Orono. He was graduated with high honors in 1906, receiving the degree of Bachelor of Science in Civil Engineering. While in college he became a member of the honorary engineering fraternity, Tau Beta Pi, and the honorary scholastic fraternity, Phi Kappa Phi.

---

[1] Memoir prepared by Henry L. Doten, M. Am. Soc. C. E.

After graduation, he spent six years in the U. S. Reclamation Service, working on the Garden City, Minidoka, Blackfeet, Flathead, Shoshone, and Sun River projects in Montana and Wyoming and advancing to the positions of resident engineer on construction and location engineer on trunk drainage ditches, and canals.

In 1912 Mr. Glover returned to the East and entered the University of Maine as a graduate student. The degree of Master of Science in Civil Engineering was conferred upon him in 1913.

During the next few years, he held engineering positions with several different companies, notably the Bangor and Aroostook Railroad Company, the International Paper Company, and the Barahona Sugar Company in Santo Domingo, Cuba. On the latter project he was the engineer in charge of the construction of a large sugar plantation.

In 1921 he returned to his native state and accepted the position of resident engineer on concrete bridge construction for the Bridge Division, Maine State Highway Commission. He served in this capacity until the winter of 1923.

During the next six years he held engineering positions with Murrie and Company, New York, N. Y.; McCrossin and Company, New York; and Structural Gypson Company, Linden, N. J. He was also office engineer on the Buggs Island Project of the Electric Bond and Share Company at Clarksville, Va.

In August, 1929, he reentered the employ of the Bridge Division, Maine State Highway Commission, and during the next two and one-half years was resident engineer on several important and difficult bridge projects.

In February, 1932, he was invited to accept a position with the City of Bangor, which had just adopted the city manager form of government. He served the city as assistant engineer for ten months and was then appointed to the position of city engineer, serving in this capacity until April 5, 1941, when he resigned because of failing health. While in Bangor, he had a summer home in the Village of Harrington and, upon his retirement, adopted this town as his permanent residence. It was his hope to indulge in his lifelong hobbies of hunting, fishing, and gardening, but fate decreed otherwise and Mr. Glover succumbed to a heart attack on May 30, 1941.

Although an unusually brilliant engineer, it may well be said that his outstanding characteristics were devotion to duty, loyalty to his superiors, and friendliness and helpfulness to his associates and subordinates. There are many engineers who will remember the kindly acts and the professional advice and assistance that helped them along the difficult pathways of engineering experience. He was always keenly interested in younger engineers and, prior to 1936, served several years as contact member with the Student Chapter of the Society at the University of Maine. While residing in Bangor, he frequently attended the chapter meetings at the University, often contributing to the program.

Mr. Glover was a member of the Masonic Order, Beta Theta Pi fraternity, and a life member of the National Geographic Society. He was also a patror of the Smithsonian Institution.

He is survived by his widow, Zena Talmage Glover, to whom he was married in 1926; a brother, Russell; and a stepson, Thomas Nickerson.

Mr. Glover was elected an Associate Member of the American Society of Civil Engineers on February 6, 1912.

ARTHUR GREEN, Assoc. M. Am. Soc. C. E.[1]

Died April 6, 1942

Arthur Green was born in Edwina, Cocke County, Tenn., on March 25, 1890, the son of Joseph D. Green and Melissia (Burke) Green. His early education was received in the public schools of Newport, Tenn., and Maryville Polytechnic School in Maryville, Tenn.

In September, 1915, he secured employment as rodman with the Aluminum Company of America in Alcoa, Tenn., and subsequently was promoted to chief instrumentman. He remained with this company until May, 1918, when he entered the United States Army. He was in the Army until February, 1919, and then returned to the Aluminum Company of America at Alcoa as instrumentman on water lines, reservoir construction, street locations, grades, and sanitary and storm sewers.

In January, 1921, he was employed at Hopewell, Va., as material estimator for the Tubize Corporation and remained there until August, 1922, at which time he resigned to accept a position as instrumentman and assistant to the city engineer of Petersburg, Va. He was in charge of the Mapping Section of the Engineering Division, and also directed the installation of water and sewer systems throughout the city. In August, 1923, he resigned from his position at Petersburg to accept employment as resident engineer with the Ambler Engineering Company of Richmond, Va., and was sent to Bristol, Tenn., to supervise and direct the surveys, planning, and installation of a filter plant for the Bristol City Water Works. In January, 1924, he was appointed city engineer of Bristol, and held this position until June, 1931. During this period he planned and directed a large street improvement program and water and sewer extension, and installed the first garbage collection system for the City of Bristol.

His good record as city engineer was accepted by the citizens of Bristol, in that he was chosen as their commissioner of streets and public improvements in June, 1931, and served until June, 1937. During these six years as city commissioner his service to the community was outstanding, as indicated by city progress. He designed and supervised construction of the Bristol City Municipal Stadium during the early years of the relief program under the Emergency Relief Administration and the Work Projects Administration. This stadium was an outstanding achievement in stone masonry of medieval architecture, and will remain as a monument to him through the years for his foresight and vision in fulfilling the needs for a recreational center for the entire city of Bristol and the surrounding territory. During his term of office he also initiated the first Civil Works Authority project in the United States in the design and construction of the Beaver Creek Channel change, thereby relieving the business section of Bristol from damage caused by flash floods, which for years had been a menace to the city.

---

[1] Memoir prepared by Robert L. Morrison, Assoc. M. Am. Soc. C. E.

In June, 1937, he established in Bristol an office for the practice of engineering and until his death on April 6, 1942, he continued to serve his community by making engineering plans and surveys for the construction of projects that will benefit mankind for many years to come.

On December 22, 1920, Arthur Green was married to Mildred Manges, of Maryville, who survives him. They had no children. He is also survived by four brothers, W. Bartley Green, John Green, Isaac Green, and George W. Green; and by two sisters, Charity (Mrs. L. B. Allen), and Flossie (Mrs. R. D. Bland).

He was a member of the Board of Deacons of the First Presbyterian Church of Bristol, and was deeply interested in his church and community affairs. He was an active member of the Kiwanis Club, the Elks Club, and the American Legion.

Time has not lessened the difficulty of consoling relatives and friends who have lost a companion and counselor, and Arthur Green's relatives and many friends can take comfort in the worthy life he lived and the assistance he gave to his fellow men.

Mr. Green was elected an Associate Member of the American Society of Civil Engineers on June 10, 1929.

CLAUDE CLEMENT HOCKLEY, Assoc. M. Am. Soc. C. E.[1]

DIED MARCH 4, 1941

Claude C. Hockley lived intensely. He was a man of strong convictions and exceptional energy. He was not an egotist, but he believed in his ability to accomplish. He was never satisfied to drift along but was always looking for more attractive fields of endeavor. When confronted with engineering or executive problems, he was not content until he had studied all phases of the subject and had arrived at a solution which, to him, appeared to be the only logical one. Early in his professional career he became an executive in responsible charge of important projects. One of his outstanding traits was the ability to win the loyalty of those under his supervision. He was exacting in his requirements, and did not spare his men or himself. The determination to give all his energies to each problem was largely responsible for his untimely death.

---

[1] Memoir prepared by M. E. Reed, M. Am. Soc. C. E.

Claude Clement Hockley was born in Watsontown, Pa., on July 5, 1878, the son of Jacob and Elizabeth Hockley. He attended the public schools of Pittsburgh, Pa., and was graduated from Ohio Northern University, at Ada, Ohio, in 1904 with the degree in Civil Engineering.

His professional life can be segregated into four periods. The first one was the formative period. It includes his college life and the railroad location and construction period before and after college. Like many engineers of the 1890's, he turned to railroad work as a means of earning a livelihood until a more acceptable type of engineering was available.

From 1899 to 1901 Mr. Hockley was a chainman, leveler, and transitman for the Carnegie Steel Company at Rankin, Pa. In 1902 he worked for the Greene County Railroad Company. The following year he became chief of party for the Wabash Terminal Railroad Company, where he remained until 1905, when he became locating engineer for the Western Maryland Railway Company. He remained with the latter company for a year, and in 1906 accepted a position as engineer for the Davis Coke and Coal Company at Fairmont, W. Va.

The second period of Mr. Hockley's career dates from 1906 when he gave up railroad work to become resident engineer for the Shawinigan Water and Power Company at Shawinigan Falls, Quebec, Canada. His duties included the installation of a 10,500-hp turbine and generator, together with head gates, penstock, and transformers. He also acted as borough engineer for Shawinigan Falls.

In 1908 Mr. Hockley was appointed chief engineer of the Laurentide Paper Company at Grand Mère, Quebec, Canada, in charge of engineering and construction. In 1910 he was also made superintendent of the Sulfite, Acid, and Wood Departments. His executive ability was soon demonstrated in the reorganization and extension of the several subsidiary companies. Surveys were made which resulted in the construction of the St. Maurice Power Company (175,000-hp capacity). He also acted as city engineer of Grand Mère, in charge of the water supply system, sewers, and pavements. A 4,000-hp steam plant was built under his supervision. In 1915, as chief engineer and mill manager for the Union Bag and Paper Company, he was in charge of properties both in Canada and the United States, including the St. Maurice Paper and Pulp Company, at Cap Madeleine Falls, Quebec, Canada, the bag factory and paper mills at Hudson Falls, N. Y., and a large bag storehouse at Wausau, Wis.

In addition to the foregoing projects, Mr. Hockley designed and built a water supply and filtration plant at Fenimore, N. Y.; built a 3,000-hp steam plant and a 50,000-kw turbogenerator at Fenimore; designed and rebuilt the paper bag factory at Hudson Falls; and rebuilt Mill No. 5 at Hudson Falls.

In 1917 Mr. Hockley was made chief engineer and manager of manufacture for the Thilmany Pulp and Paper Company in Kaukauna, Wis., and also for its subsidiaries, including the Paper Conversion Corporation at Niagara Falls, N. Y., and the American Lakes Paper Company at Waukegan, Ill. He was in charge of reconditioning the paper mills at Appleton and Kaukauna, Wis., of the construction of a 5,000-kw turbogenerator at Kaukauna, and of the construction of a two-machine mill at Niagara Falls for manufacturing and printing waxed waterproof paper. Mr. Hockley invented and patented several improvements in paper-mill operation.

The third period in his career dates from 1925 when he opened a consulting engineering office in Portland, Ore., specializing in power development and paper-mill design. A special study was made of the possibility of using mill refuse in pulp manufacture and also for wallboard. Studies also were made for hydroelectric power developments in the Northwestern States and Alaska. While making these studies, Mr. Hockley was retained by paper mills and other corporations in the Northwest.

The fourth period of Mr. Hockley's career began in 1933 when he was appointed regional director of Region No. 9 of the Public Works Administration, in charge of projects in Oregon, Washington, and Idaho. These projects covered a broad field of engineering and architecture with costs running into many millions of dollars.

Mr. Hockley's executive ability was soon demonstrated in the organization of the personnel that was required to complete this large program. Perhaps the most difficult problem was to keep the relations among the engineers, the contractor, and the owner harmonious and at the same time meet the requirements of the Washington officials. Mr. Hockley was able to meet the problems as they arose and eventually to win the confidence of all involved.

On October 5, 1910, he was married to Edith Moore. He is survived by his widow, a son, Claude C., Jr., and a daughter, Helene.

Mr. Hockley was elected an Associate Member of the American Society of Civil Engineers on April 2, 1912.

WILLIAM LOUIS KUEHNLE, Assoc. M. Am. Soc. C. E.[1]

DIED FEBRUARY 8, 1942

William Louis Kuehnle was born in New York, N. Y., on March 1, 1881, the son of George W. and Bertha L (Pratt) Kuehnle. He attended Rutgers College at New Brunswick, N. J., and received the degree of Bachelor of Science in 1902. In 1911 he received the degree of Civil Engineer.

His first engineering experience was gained during the summer of 1901, when he was employed as an instrumentman on hydrographic surveys by the Corps of Engineers in the New York District Office. After graduation he returned to the Corps of Engineers, this time as assistant to the chief inspector on dredging and timber bulkhead construction at Philadelphia, Pa. From this time until the end of his life, Mr. Kuehnle served with the Corps of Engineers, except for a short period spent in private practice and with an industrial concern. From 1903 until 1923, he was stationed at the U. S. Engineer Office, First District, New York City, where he served in various capacities, with steadily increasing responsibility. During this time he laid the groundwork for his broad experience in both construction operations and design. His assignments included surveying, inspection, construction, design of various types of navigation projects, dredging, and other aspects of the work done by the Corps. He also organized the cost-accounting system used in this District Office.

---

[1] Memoir prepared by Norman H. Chaffee, Chf. Administrative Asst., U. S. Engr. Office, Tulsa, Okla.

In 1923 Mr. Kuehnle severed his connection with the Corps of Engineers to enter private practice at Long Beach, N. Y. His engagements during this period were in many fields, including town planning, design and construction of municipal improvements (such as sewers and streets), the design and construction of building foundations, beach erosion, and structures. Late in 1928 he was engaged by the Dry Ice Corporation of America as chief engineer on the design, construction, and operation of plants for the manufacture of dry ice or solid carbon dioxide.

In 1931 he again entered private practice for a short period but was prevailed upon to rejoin the Corps of Engineers in the Pittsburgh, Pa., District Office, where he remained until 1936. In the Pittsburgh Office he was in charge of all contract and hired labor construction and inspection and was acting principal engineer in the absence of the principal engineer. In 1936 Mr. Kuehnle was transferred, first to Galveston, and then to Mineral Wells, Tex., as acting principal engineer on design and investigations for the Possum Kingdom Dam on the Brazos River. In 1937 he was again transferred, this time to the Binghamton, N. Y., District, where he was in charge of the design of earth-fill dams and levees and flood-wall projects for five localities. Mr. Kuehnle transferred to the Little Rock, Ark., District in 1938 to take charge of the Operations Division in that office. In this position he was responsible for all contract inspection and hired labor operations on the structures being built under the supervision of that office. He also was in charge of safety, land acquisition, and labor relations. In July, 1939, a new District Office was formed at Tulsa, Okla., where Mr. Kuehnle was stationed at the time of his death. Mr. Kuehnle went to the Tulsa District Office as principal civilian assistant in charge of the Engineering Division. He was responsible for all phases of investigations and engineering studies in the design and construction of major flood-control dams and reservoirs. Upon the transfer of Air Corps construction to the supervision of the Corps of Engineers, he assumed charge of the design and construction of all such projects assigned to the Tulsa District.

Mr. Kuehnle was an able engineer. He had good judgment and common sense, and was honest and extremely conscientious. He took a keen interest in all phases of the work being performed under his supervision, and due to his large and varied experience was able to give helpful criticism. He possessed an ability to express himself forcefully and aptly, with a sense of humor that aided in keeping a balanced view of the many problems presented to his attention. His death, following an automobile accident on February 7, 1942, near Watonga, Okla., leaves a vacant place which cannot soon be filled. Men of his ability cannot well be spared in this time of need.

He was married in 1906 to Luella Mae Van Dusen, who survives him. A brother and two sisters also survive him.

Mr. Kuehnle was elected an Associate Member of the American Society of Civil Engineers on June 6, 1911.

ENGELBERT CONRAD LAWRENCE, Assoc. M. Am. Soc. C. E.[1]

Died October 25, 1941

Engelbert Conrad Lawrence was born in Baltimore, Md., on June 11, 1875, the son of Joseph and Isabelle (Scott) Lawrence. He was educated at St. Michaels Parochial School in Baltimore; took business courses at St. Clements College in Saratoga Springs, N. Y., and St. Marys Seminary at North East, Pa.; studied engineering in the International Correspondence School; and studied architecture at the Maryland Institute of Art and Design.

In 1892, when only 17 years old, he began his technical career as an estimator with one of the largest and best-known contracting firms in Baltimore. Before he left this firm, after about four years of service, he had had charge of the construction of some buildings.

From that firm he went to a large bolt and steel works in Baltimore for three years and was in charge of its Estimating and Drafting Department. Following this work he became an estimator and detailer of structural steel for buildings with the Baltimore Bridge Company and then with Purdy and Henderson of New York, N. Y. He was with each of these companies for about a year, and then was engaged by an important Baltimore building contractor to take charge of the Estimating Department and act as superintendent of construction. In his five and one-half years of service for this company he designed and constructed buildings costing more than a half million dollars. He left that firm to go to the Engineering Department of the Baltimore and Ohio Railroad Company as a designer of bridges and foundations. In July, 1907, after only about six months of service there, the Harbor Board of Baltimore selected him as engineer on the construction of a $5,000,000 pier and improvement project for that city's harbor. After about eight months he was promoted to the position of principal assistant engineer in charge of this work. About four years later, when the work was practically finished, he went with a large general contracting firm in Newport News, Va., as an estimator and engineer.

---

[1] Memoir prepared by Alfred M. Quick, M. Am. Soc. C. E., and Charles W. Wisner, Jr., Asst. Director, Claim Dept., U. S. Fidelity and Guaranty Co., Baltimore. Md.

After about a year's service with this firm, he was appointed by the United States Fidelity and Guaranty Company as an engineer and adjuster in its Claim Department, and there he began the final link in his chain of forty-two years of continuous technical service. His period of service in this company exceeded by two years the total of all of the periods of his previous service. This work required all his knowledge and skill as an engineer plus the practical and working knowledge of the rights and duties of a surety in a bond conditioned for the faithful performance of a construction contract. It involved the duty of protecting the rights of the obligee, or owner, seeing that he received all that his contract called for, and at the same time conserving the interests of the principal—that is, the contractor.

This line of work took Mr. Lawrence into every section of the United States. In almost every state there are roads, schoolhouses, dams, water works, sewerage systems, post offices, memorial structures, and many other constructions of various types, which were built either under his supervision or under his general direction. Space is not available to enumerate even the most outstanding of these, but to mention a very few, there are: The Soldiers and Sailors Memorial Auditorium, Chattanooga, Tenn.; high school building, Waynesburg, Pa.; Seattle (Wash.) water works; sewerage system, Westchester County, New York; Concourse Apartments, New York City; Post Office, Brooklyn, N. Y.; the Wills Creek Dam, Zanesville, Ohio; and pier, bulkhead, and ramps, Naval Air Station, Jacksonville, Fla.

This work brought Mr. Lawrence into contact not only with other engineers, architects, and contractors, but also with various governing bodies and commissions of the school district, the county, the state, and federal authorities; with the lawyers representing all these; and with bankers and financial representatives, often in consultation, not infrequently in contest—a work which was broadening but which required fundamental ability and acumen. Mr. Lawrence measured up to these requirements.

In his later years Mr. Lawrence was frequently engaged as a consulting engineer. On many occasions his services as supervisor of construction work were sought, but he always refused because of possible conflict with his company duties.

He died on October 25, 1941, a character of sincerity and reliability, a hard worker, clear-headed, and able to concentrate, with a gift and developed ability of sound reasoning which brought sound conclusions. He was a man of diligence, great energy, and vitality.

To the home there has been the irreparable loss of husband and father; to the company there has been the loss of a most able representative in one of the most important phases of its business; to many, the loss of a dependable friend; to his profession the loss of an able and experienced engineer, one who strove to maintain and maintained the high intent of his profession and his Society.

Mr. Lawrence was married to Anne Heyer of Baltimore on October 13, 1896. She died on June 23, 1915, leaving five children: Three daughters, Isabelle (Mrs. William A. Fingles, Jr.); Genevieve (Mrs. Charles I. Jamieson); and Anne (Mrs. Edward J. Donnelly); and two sons, Edgar C. Lawrence, and John Heyer Lawrence, Assoc. M. Am. Soc. C. E. Also surviving

Mr. Lawrence are his second wife, Rachel Mills of Baltimore, to whom he was married on September 28, 1916, and nine grandchildren.

Mr. Lawrence was elected an Associate Member of the American Society of Civil Engineers on November 8, 1909.

THOMAS JOSEPH LEAHY, Assoc. M. Am. Soc. C. E.[1]

Died August 8, 1940

Thomas Joseph Leahy was born in Central City, Colo., on September 3, 1879, the son of Marcus Leahy and Hanna (Foehy) Leahy, a pioneer mining family of Central City. He received his education in the public schools of Central City and was graduated from the Central City High School.

His engineering career started in March, 1903, with employment as chainman on a surveying party for the Denver, Northwestern and Pacific Railroad Company—that famous 50-mile section of line between Denver, Colo., and the Continental Divide, having twenty-nine tunnels, then under construction. Mr. Leahy rose rapidly from chainman to instrumentman on construction, having charge of work. He remained with the railroad until March, 1909.

After several short engagements on irrigation and railroad survey work, and construction on the Juniper Coal Company property, he became resident engineer on survey and construction of water conduits, and other work for the Denver Union Water Company. With the sale of the water plant to the City of Denver, on November 1, 1918, he was retained by the Denver Board of Water Commissioners as construction engineer until June, 1926. During this period of nearly sixteen years, Mr. Leahy had charge of the surveys and construction of six large, steel, concrete and wood stave conduit lines, forming an important part of Denver's water supply system. He also had charge of the construction of a diverting dam, and other important structures.

In 1927 and 1928, Mr. Leahy was resident engineer on the construction of 200 miles of railroad for the Fort Worth and Denver South Plains Railway Company in western Texas. From 1929 to 1939 he was employed on many short engagements, mostly in or near Denver, involving the construction of stockyards, hospital buildings, sewers, a swimming pool, South Platte River improvement, and other work, being employed by the Denver Union Stock Yards, the Public Works Administration, and the Work Projects Administration.

Mr. Leahy was one of the first members of the Colorado Society of Engineers. He was a member of the Roman Catholic Church.

In 1910 he was married to Agnes Flynn. He is survived by his widow; two sons, Thomas C. and Marcus C.; one daughter, Florence Leahy; one brother, Richard; and two sisters, Margaret (Mrs. Frank Jones), and Mary (Mrs. John Hughes). He was highly respected by all who knew him.

Mr. Leahy was elected an Associate Member of the American Society of Civil Engineers on October 1, 1913.

---

[1] Memoir prepared by Dwight D. Gross, M. Am. Soc. C. E., and Arthur A. Matthews, Esq.

JAMES BELL LEIGH, Assoc. M. Am. Soc. C. E.[1]

Died February 16, 1942

James Bell Leigh was born in Columbus, Miss., on April 21, 1893, the son of William F. and Julia (Riddick) Leigh.

He received his grammar and high school education in Columbus. In 1910 he was graduated from Franklin Academy (Columbus) as valedictorian of his class. Then he was employed for a year as clerk in a drug store, Weaver and Harrington, in Columbus, and one year as clerk in the Yarborough Hotel, Raleigh, N. C.

He entered Vanderbilt University, Nashville, Tenn., in 1913, and was graduated in 1917 with the degree of Bachelor of Science in Engineering. Here he completed both the civil and mechanical engineering courses and was graduated cum laude, in spite of the fact that he was doing outside work to help defray the expenses of his college education. In his senior year he taught chemistry classes in the University.

Franklin Academy received affiliation with Vanderbilt University and entrance examinations were waived on account of the high record of James Bell Leigh on his entrance examinations and his work at Vanderbilt, by letter written from Vanderbilt University to Franklin Academy.

From June 1 to September 30, 1917, he was employed as engineer for the Suwanee Iron Company, superintending the reconstruction of two blast furnaces and the housing and sanitary facilities for the workmen at Grand Rivers, Ky. From September 30 to November 30, 1917, he was assistant engineer for the Hillman Land and Iron Company, supervising the surveying of land, establishing permanent corners, locating prospect holes, and surveying and staking out roads on the extensive holdings of this company in Kentucky with headquarters at Kuttawa, Ky.

From November 30, 1917, to April 4, 1918, he was employed as Arkansas representative, with headquarters at Jonesboro, Ark., for Klyce and Kackley, Engineers of Nashville, supervising the surveying, designing, inspecting and testing materials, and the construction of highways, municipal improvements, and drainage canals. He was in charge of work amounting to six million dollars at one time.

During World War I, from April 4, 1918, to July 21, 1919, he was in the U. S. Army Engineer Corps, 43d Engineers, which was afterward combined with the 20th Engineers, at St. Julien-Clensy, France. He was acting master engineer, repairing roads, etc., and on special detached service, serving in active duty in France for more than a year during this period.

From July 21, 1919, to June 1, 1923, he was again engineer in Arkansas for Klyce and Kackley with the same duties as before. From June 1, 1923, to August 1, 1925, he was chief construction engineer and principal assistant to chief engineer in charge of all field work and construction for Mississippi

---

[1] Memoir prepared by William F. Leigh, Pottsville, Pa.

County Road Improvement District No. 1, building 58 miles of concrete and bituminous highway, and paving, storm sewers, curbs and gutters through six towns, From August 19, 1925, to September 1, 1925, he was engineer for Magehee, Ark., acting as consultant in designing. He supervised the construction of a sewage system and reinforced concrete sewage disposal plant, consisting of approximately eleven miles of 8 in. T.C. gravity sewer, one mile of 15 in. T.C. pressure sewer, one ejector pit with a 50-gal ejector, one pit with two 300-gal ejectors, one reinforced concrete double-chamber Imhoff tank, filter beds, etc.

From September 1, 1926, to June 1, 1931, he was employed as resident engineer, assistant district engineer, and district construction engineer for the Arkansas Highway Department, first in District No. 1 comprising nine counties and then in District No. 2 comprising eleven counties. He was in charge of all the construction work of an extensive construction program of the Highway Department in these districts. This included different types of highways, such as gravel, bituminous, concrete, etc., and such bridges and causeways, etc., as the Harrihan Viaduct, which is the 2¾-mile earth and concrete approach on the Arkansas side to the Harrihan Bridge at Memphis, Tenn.; the White River Bridges with the 4-mile approach at Clarendon, Ark., a reinforced concrete and steel high-arch bridge; the bridges and approaches at DuValle Bluff, Ark., on the U. S. Highway No. 70; and many others.

From December 1, 1931, to April 30, 1933, he was employed as contractor's engineer for the Merit Concrete Corporation, and was in charge of the engineering work on reinforced concrete arches, concrete deep foundation walls, etc., on ten new buildings for the New York Hospital at Wingdale, N. Y., and five new buildings for the New York State Hospital at Creedmore, Long Island, also on part of the reinforced concrete work for the New York Central Railroad overhead approach to the Parcel Post Building in New York, N. Y.

From April 30, 1933, to March 1, 1934, he was employed as professional superintendent in charge of CWA work at Langley Field, Virginia. This included remodeling work on wind tunnels, moving and building shops, etc.

He was employed from March 1, 1934, to January 1, 1935, as contractor's engineer in charge of the engineering work for the Washington Concrete Corporation of New York City on concrete fireproofing, cinder arches, reinforced concrete arches, concrete foundations, etc., on Knickerbocker Village, and the Italian Building, Radio City.

From February 16, 1936, to September 29, 1936, as project head, he was in charge of the Schuylkill River Survey for the Work Projects Administration (WPA) in Schuylkill County, Pennsylvania, in cooperation with the United States Engineer Department. From September 29, 1936, to March 13, 1938, he was employed as project head and project engineer for the WPA, in charge of a complete survey map for the City of Pottsville, Pa. From March 13, 1938, to the time of his last illness he was employed as assistant engineer, Classification 1, with Pennsylvania State Office of WPA, Special Consultant on Highway and Air Port Construction.

With his brilliant mind, superior ability, and conscientious application to all duties and responsibilities, he gave much to the world; but those who mourn his passing think most of his modesty, his unselfishness, his clever original wit, his nobility of character, and the quiet unassuming way in which he did for others. He bore misfortunes unflinchingly and alone, never asking others to share them; and what evil and wrong he discovered in others, he kept absolutely to himself.

It seemed especially fitting, because of his unswerving patriotic spirit, that he should be given a funeral with full military honors which his Forty and Eight and Legionnaires Comrades requested.

He was a Mason, a Shriner, an Elk, and a member of the American Legion and the Forty and Eight.

Mr. Leigh was elected an Associate Member of the American Society of Civil Engineers on January 15, 1923.

ROY EZEKIEL NELSON, Assoc. M. Am. Soc. C. E.[1]

Died January 7, 1941

On August 29, 1889, Roy Ezekiel Nelson was born at Halleck, W. Va. He was the tenth of eleven children of David and Melinda (Galliher) Nelson. Mr. Nelson's early life was spent on the farm where he developed his love of the outdoors and sports.

In 1913 Mr. Nelson was graduated from Fairmont State Normal College, in Fairmont, W. Va. Previous to his graduation, and interspersed with his studies, he taught in the public schools for a period amounting to about four years. Until interrupted by the first World War, Roy Nelson continued to pursue his education at West Virginia University, in Morgantown.

When the United States declared war, he was one of the first three in Monongalia County to volunteer for service. At first he was rejected because of a weak hip that had developed since childhood, but upon continued persistence he was admitted to the service of his country on September 5, 1917, and sent to Camp Lee, Virginia, where he was assigned to duty in the Field Artillery, and subsequently was graded as corporal.

On May 26, 1918, Corporal Nelson sailed for Europe. Upon arriving there he was trained at the artillery school in Saumur, France. When the war was over, Corporal Nelson was honorably discharged from the 314th Division of the Field Artillery and thereupon commissioned a Second Lieutenant of Field Artillery on March 23, 1919.

Once again Mr. Nelson continued his pursuit of education, and in 1921 received the degree of Bachelor of Science in Civil Engineering from West Virginia University. In February of the same year he joined the faculty of his alma mater as instructor of surveying.

The year of 1925 proved to be an outstanding one in Mr. Nelson's career, for in this year he received his Master's Degree in Civil Engineering from the

---

[1] Memoir prepared by Richard T. Feller, West Virginia Univ. Student Chapter, Am. Soc. C. E., Morgantown, W. Va.

University, and also a Master's Degree in Highway Engineering from Iowa State College, in Ames. On gaining these honors he was promoted to assistant professor of railway and highway engineering, in which position he served until his sudden death.

Professor Nelson always occupied his summers very profitably, such as in 1930 when he served with the U. S. Engineers on dam and flood-control surveys. During the summers of 1935 to 1940 he was manager and instructor of the University's surveying camp.

In September, 1938, Professor Nelson was married to Dorotha Armstrong, a friend of many years standing, by whom he is survived. He is also survived by two sisters, Iva and Bessie (Mrs. James W. Boyers); and two brothers, George H. and Edward M. Nelson.

Professor Nelson took a great interest in the Masonic Order. He earned his Thirty-Second Degree and was a past master of Morgantown Union Lodge No. 4, A. F. and A. M. He was also a member of the American Society of State Highway Officials.

In the twenty years that Professor Nelson served the University as a teacher and adviser, he made contacts and associations that resulted in lasting friendships with many men now in the engineering profession who mourn his departure. His close association with members of the teaching profession repeatedly demonstrated his sterling qualities of friendship, honesty, and integrity. Although handicapped by a physical infirmity that caused him great suffering in the later years of his service, he always maintained a disposition to keep going under circumstances that would cause many men to falter and fail.

Professor Nelson was elected an Associate Member of the American Society of Civil Engineers on September 18, 1939.

HARLAN ROWE ROBBINS, Assoc. Am. Soc. C. E.[1]

DIED MAY 22, 1941

Harlan Rowe Robbins was born in Owosso, Mich., on August 15, 1893, the son of William V. and Lillian (Sargent) Robbins. In 1916 he was graduated from the School of Mines of the University of Utah, in Salt Lake City, with the degree of Bachelor of Science in General Engineering.

His father is associated with the mining industry, and Mr. Robbins' early work was in that field. For two years after leaving college he was manager and foreman of the Metallurgical Laboratory of the General Engineering Company in Salt Lake City. During the first World War he served in the Signal Corps of the United States Army and was given a special Signal Corps Officers' training course at Yale University, in New Haven, Conn. After the war he returned to Utah, and in 1919 served as a shift boss for the Western Utah Copper Company, followed by the position of foreman on structural contracting work. In the early part of 1920 he worked as a shift boss for the Vipont Silver Mining Company in Idaho.

---

[1] Memoir prepared by a Committee of the Sacramento Section consisting of A. G. Mott, M. Am. Soc. C. E., Chairman, Walter E. Stoddard, Assoc. M. Am. Soc. C. E., and Thomas B. Waddell, M. Am. Soc. C. E.

In June, 1920, he moved to California and was appointed an assistant engineer with the California Railroad Commission. The Commission has under its jurisdiction the regulation of public utilities in the State of California, including water, telephone, telegraph, electric, gas, railroad, and other privately owned public utilities. Its duties include fixing rates and granting reparations for excess charges, the determination of the need for utility service, the granting of certificates of public convenience and necessity where such need exists, the control of utility financing, the authorization for the disposal of utility property, and the fixing of just compensation for property taken under condemnation. During the fourteen years that Mr. Robbins was with the Commission, he prepared appraisals of lands, leaseholds, right of ways, easements, and franchises to assist the Commission in the foregoing duties and in other duties when appraisals were directly or indirectly involved.

In 1933 California adopted a major change in its tax system, which required the appraisal for tax purposes, for the first time in twenty-five years, of all properties of public utilities. For this purpose the Valuation Division of the State Board of Equalization was created, and Mr. Robbins was chosen as one of the most qualified land appraisers in California to take charge of the land valuation work of the Division for this major task. This work required the appraisal each year of many classes of lands widely situated throughout the State of California and having an aggregate value in excess of $200,000,000. In this work he won for himself a reputation of outstanding ability.

At the time that he took up his duties with the Valuation Division, Mr. Robbins moved to Sacramento, Calif. He resided there until the time of his death, which occurred very suddenly while he was away on a business trip in Los Angeles, Calif.

Mr. Robbins had various outside interests and hobbies, among which were rifle marksmanship, amateur photography, and astronomy. In following the latter subject, he developed an interest in lenses and telescope manufacture, and contributed in no small measure to the development of amateur interest in astronomy in his community because of his ability in grinding and mounting lenses.

In 1917 he was married to Ethelyn Slater in Salt Lake City. He is survived by his widow and parents.

Mr. Robbins was elected an Associate Member of the American Society of Civil Engineers on July 25, 1932.

EARL MILTON SPENCER, Assoc. M. Am. Soc. C. E.[1]

DIED JANUARY 7, 1941

Earl Milton Spencer was born at Topeka, Kans., on February 25, 1889, and died on January 7, 1941. He was the son of Francis Milton Spencer and

---

[1] Memoir prepared by F. W. Epps, M. Am. Soc. C. E.

Catharine (Miller) Spencer. His early education was obtained in the public schools of Topeka, after which he attended Washburn College, in Topeka, for two years, where he took the engineering course.

From January, 1910, to November, 1911, he was superintendent and engineer for his father, who was a general contractor. From 1911 until the time of his death he was owner of the firm of F. M. Spencer and Son, General Contractors. During this time Mr. Spencer was in charge of the following large contracts:

1924—Capital Building and Loan office building at Topeka
1924—Parsons High School Building at Parsons, Kans.
1926—Central National Bank and Trust Company at Topeka
1926—Ursuline Academy at Paola, Kans.
1927—Mutual Ice and Cold Storage Company at Topeka
1930—Hospital at Topeka for Security Benefit Association
1930—Clear Water Reservoir at Topeka
1930—Residence for Mrs. Frank P. MacLennan at Topeka
1931—National Bank of Topeka
1934—Depot for Atchison, Topeka and Santa Fe Railway Company at Oklahoma City, Okla.
1938—Residence for Alfred M. Landon, at Topeka
1938—Municipal Auditorium and offices at Topeka
1939—Residence for Mrs. Dan L. Meisinger at Topeka
1939—Manufacturing Building for John Morrell and Company at Topeka

All of these contracts were executed faithfully and honestly.

On April 17, 1912, Mr. Spencer was married to Zella Chapin. Two children were born to this union, Mary Catharine and Francis Milton. His wife and the two children survive him.

Mr. Spencer was elected an Associate Member of the American Society of Civil Engineers on January 16, 1922.

JOHN JOSEPH SWEENEY, Assoc. M. Am. Soc. C. E.[1]

DIED JANUARY 6, 1942

John Joseph Sweeney, the son of Patrick M. Sweeney and Mary (Morrow) Sweeney, was born in Eckley, Pa., on February 28, 1889. He attended the public school and his college preparatory work was taken at the Mining and Mechanical Institute of Freeland, Pa., where he was graduated with honors in June, 1907.

After graduation, from June, 1907, to September, 1908, and the subsequent summers of 1909, 1910, and 1911, he worked as a rodman, chainman, transitman, and chief of party for the G. B. Markle Coal Company of Jeddo, Pa.

In September, 1908, Mr. Sweeney entered Villanova College at Villanova, Pa., and was graduated in 1912 with the degree of Bachelor of Science in Civil Engineering. He received the degree of Civil Engineer from Villanova in

---

[1] Memoir prepared by Wilmer Z. Kline, M. Am. Soc. C. E.

June, 1918. While at college Mr. Sweeney was active in the Phi Kappa Pi Society and was a member of the track team.

After graduation he obtained a position with the New York Central and Hudson River Railroad Company as a rodman, inspector, and field engineer on its property subdivision work on grade-crossing elimination, remaining there until November, 1913. He then entered the employ of Villanova College as instructor in the Civil Engineering Department. In 1914 he became an associate professor in the Civil Engineering Department, and in 1917 he was appointed professor of highway engineering. He taught at the College in the latter capacity until June, 1930.

While teaching, Mr. Sweeney went into the practical field of engineering each summer and gained much engineering experience. In the summer of 1914 he traveled in Europe and was there when the first World War started.

From June to September, 1915, he worked as an assistant engineer for the Lehigh Valley Coal Company on the valuation of coal lands. He spent his vacations in 1916, 1917, 1918, and 1919 as superintendent for H. P. Friend, Inc., Engineers, of Norristown, Pa., on general building construction, railroad construction, estimating and street paving.

Mr. Sweeney spent the summer of 1920 in travel. During the vacation periods of 1921 and 1922 he taught summer school at Villanova College. In the summer of 1923 he acted as inspector of building materials, steel, stone, concrete, and concrete highways for the Highway Department of Monmouth County, New Jersey. During vacations in 1924, 1925, and 1926, he worked on land development and subdivision work, laying out the Merion Golf Manor tract for Over and Tingley at Oakmont, Pa. In the summer of 1927 Mr. Sweeney was resident engineer on the stadium construction at Villanova College. During the following two summers he was resident engineer for Carl R. Camp, Inc., on roads and bridge construction.

In June, 1930, after much deliberation, Mr. Sweeney gave up teaching to accept membership in the firm of Carl R. Camp, Inc., Engineers and Contractors, with whom he had been associated the two previous summers. During this association, as resident engineer, he actively supervised the construction of the Sewerage Disposal Plant for the City of Burlington, N. J., and the following bridges in Delaware County, Pennsylvania: The Fourth Street Bridge in Chester, Pa.; Waterville Bridge No. 9, Delaware County, between Nether Providence and Chester; Crozierville Bridge over West Branch of Chester Creek, Ashton Township, Delaware County; Johnsons Mill Bridge No. 11, West Branch of Chester Creek in Ashton, Pa.; and the State Bridge 22d Street in Chester, Pa.

In 1932 their contracts were all finished and a major depression was in progress; to employ his time to advantage Mr. Sweeney attended the Graduate School of the University of Pennsylvania, at West Philadelphia, from September, 1932, to June, 1933, majoring in mathematics and physics. In March, 1934, he obtained a position as general superintendent on Pennypack Park, Philadelphia, Pa., on road construction. He gave up this work in June, 1934, to become resident engineer on the construction of the State Bridge 22d Street between Ridley Township and the City of Chester.

In September, 1935, Mr. Sweeney went to the Navy Yard in Philadelphia on construction of roads, etc. In July, 1940, he was appointed associate civil engineer, a post which he held until his death.

When the construction of five large buildings in the Navy Yard was undertaken by the Public Works Administration, Mr. Sweeney was placed in charge in the field of construction of all of the buildings. This work was handled successfully and expeditiously. He was subsequently placed in charge of the specification group of the Design Section and for several years until his death he was responsible for the preparation of specifications for a large amount of construction work that was performed by bid contracts. Mr. Sweeney's part in getting various projects under contract was handled carefully and with a minimum amount of difficulties. The specifications prepared by his group were found to describe the work accurately and without conflict.

After leaving the teaching field for engineering work, Mr. Sweeney kept in close touch with the student activities at Villanova College and did much to further student participation in the Student Chapter of the Society. He served on the Student Chapter Board for many years. As a member of the Reception Committee, Meetings Committee, and the Villanova representative for Student Chapters, all of the Philadelphia Section of the Society, he was a tireless worker in the interests of the Section.

In June, 1916, Mr. Sweeney was married to Florence Marie O'Rourke of Philadelphia, who survives him.

Mr. Sweeney was elected an Associate Member of the American Society of Civil Engineers on January 16, 1922.

JAMES SYKES, Assoc. M. Am. Soc. C. E.[1]

Died August 31, 1941

James Sykes was born at Mossley, Cheshire, England, on May 18, 1884, the son of Hezekiah and Eleanor (Hollingworth) Sykes. At the age of twenty two, he was graduated from the Municipal School of Technology, in Manchester, England, and came to the United States shortly thereafter.

His first work in engineering after reaching the shores of America was that of inspector on the Sixth Avenue Extension, Hudson and Manhattan Railroad, in New York, N. Y., from April, 1907, to June, 1908. While with this company he had the experience of construction in concrete, waterproofing, excavation, timbering, and other phases covering the general scope of civil engineering as practiced on such contracts. His training in actual construction work at this time proved of great value in later years when he assumed definite responsibilities in the field of railroad engineering.

Early in the summer of 1908, he began work with the Oklahoma Strenolith Paving Company, at Oklahoma City, in the design and construction of paving machinery. This assignment led to his appointment, in October, 1909, as assistant city engineer. This work included the design and construction of sewers, a disposal plant, and other municipal works.

---

[1] Memoir prepared by Ralph L. Parshall, Assoc. M. Am. Soc. C. E.

James Sykes' ambitions and interest brought him back into the field of railroad engineering when he took up his work with the Kansas City Terminal Railway Company, at Kansas City, Mo., in January, 1912. His activities here centered on the design of classification yards and track material, together with the many other details related to the job.

To broaden his field of experience, he began work as assistant engineer with Burns and McDonald, in Kansas City, in January, 1915, and was supervising engineer on the Montrose, Kans., and Orchard City, Kans., water works system. While with this firm of engineers, he made valuation studies on public utilities and was also engaged in other important lines of engineering.

After completing his work at Kansas City, he went to Denver, Colo., in July, 1916, as engineer for the Great Western Sugar Company. Because of his experience in general railroad work, he was assigned to the engineering staff of the Great Western Railway Company, a subsidiary of the Sugar Company. His work with this company covered valuation studies, which brought him national recognition. He was given the responsibility of maintenance of the railroad, operating in northern Colorado, where the line connected with several sugar factories in the transportation of sugar beets, livestock, and other agricultural commodities. His ability in the field of railroad engineering was soon recognized and he was later made chief engineer of this important transportation line. He held this position at the time of his death.

James Sykes possessed a pleasing personality; he was ambitious—a characteristic necessary for the progressive engineer—a most excellent companion, and a true friend. His home library, of many volumes, covered a wide range of subjects that were indicative of his broad knowledge of engineering and scientific matters. His training and experience in his chosen profession made him a keen observer, a leader, and one capable of assuming responsibilities under adverse conditions. He was a treasurer of valuable old records, a correlator of the past and present general world conditions, and a traveler in his own right.

He was a lover of the great outdoors, finding both interest and pleasure in his contact with Nature. At home, he was a contented man, and prided himself on his talent for cooking and sewing. He was also a musician and painter of landscapes. His untimely death, due to a heart ailment, was a distinct shock to his many friends and close acquaintances, who suffer in the loss of a true friend and a thorough gentleman.

He was married to Emmaline Leachman, at Louisville, Ky., on April 17, 1910. There were no children. His widow survives him.

He was associated with a number of professional organizations and was a leader in local civic activities. He was a member of the Episcopal Church and of the Stayley Masonic Lodge of Stalybridge, England.

Mr. Sykes was elected an Associate Member of the American Society of Civil Engineers on January 14, 1918.

HANSON ZIMRI WILSON, Assoc. M. Am. Soc. C. E.[1]

DIED DECEMBER 27, 1940

Hanson Zimri Wilson was born on April 22, 1874, near "Brick Meeting House" on the site granted by William Penn to his followers in Nottingham, Pa. The post office, at that time called "B. M. House," was later moved to the nearest railway station at Sylmar, Md. Mr. Wilson's parents were the late William and Mary (Taylor) Wilson. His maternal grandfather, Zimri Taylor, was married to Julia Brown, whose family had been among the first settlers of Penn's Nottingham Lots in 1701. His paternal grandparents, Samuel Dixon and Mary (Pierson) Wilson, founded the homestead in Maryland, which was also property belonging to the Nottingham Lots previous to the survey of the Mason and Dixon Line in 1765.

Hanson Wilson attended Swarthmore College at Swarthmore, Pa., and in 1896 was graduated with first honor, with the degree of Bachelor of Science. Early in the following year he started on surveying work for the Erie Railroad Company at Port Jervis, N. Y. He also continued his studies in civil engineering, and prepared a thesis entitled "Railway Track Maintenance." He was granted the degree of Civil Engineer by the managers of Swarthmore College in 1899.

In 1899 Mr. Wilson became assistant engineer in charge of the Engineering Corps, Maintenance of Way Department, for the Erie Railroad Company, and had responsible assignments in Port Jervis and in Jersey City, N. J. Some of these duties were: The designing of engineering structures, re-alining and putting spiral ends on curves, preparing plans and estimates for the cost of track extensions, yard design, signaling for interlocking, new water stations, and preparing plans and laying out masonry for new bridges.

From 1901 to 1905, as supervisor for the Erie Railroad Company at Bradford, Pa., he was in charge of engineering and track foremen. He also acted as engineer and prepared plans for, and directed the building of, spur tracks, one with a 30-ft span bridge. Similar engagements until 1910 completed a continuous service of nearly fourteen years with the Erie Railroad Company.

At this time Hanson Wilson entered the employ of the Standard Oil Company of New York as engineer in its Construction Department. In 1912 he became associated with the Standard Oil Company of New Jersey. He was one of the original members of the Civil Engineering Department when it was organized in New York, N. Y. Later, with head office at Newark, N. J., he was construction engineer in charge of the design and building of domestic trade stations in the State of New Jersey. During this engagement there were favorable comments from other divisions of the company on the efficient way in which the engineering work was conducted. Mr. Wilson was one of the first to employ photography as a means of recording the progress of construction work in the field. On his retirement in 1932 he was presented with a service pin in recognition of his twenty years of service.

---

[1] Memoir prepared by C. Victor Wilson, Licensed Professional Engr., State of New York, Nassau County, Dept. of Public Works, Mineola, N. Y.

In 1921 he built a colonial dwelling in the Midwood Manor section of Brooklyn, N. Y., which became a very attractive residential district. Here he resided for nearly twenty years, making annual vacation visits to his relatives in Maryland. There were four brothers and one sister. Three of his brothers survive him. Although Hanson remained a bachelor, he was always interested in the younger generation of his relatives and friends, several of whom he assisted in obtaining an education. Others were encouraged by his timely advice when getting started on their careers in civil engineering.

Mr. Wilson was a member of the Men's Club of the Religious Society of Friends in Brooklyn, which he attended regularly for many years; he was also a member of its Friendly Hand Society. Likewise, he served on committees of the Yearly Meeting of Friends. He was fond of taking long walks with a Friend and of taking snapshots with his favorite camera, some of which he made available to the Society.

Different mathematical subjects, including astronomy, were of special interest to him. In 1935 and 1936 he attended classes in astronomy at Columbia University in New York City. At this time he became a member of the Amateur Astronomers Association, with headquarters at the American Museum of Natural History in New York City. On January 1, 1925, he took photographs of the total eclipse of the sun from the top of Bear Mountain, New York. Enlarged copies of these photographs, with details of the observation, were contributed to the Amateur Astronomers Association. Also, in 1934 he contributed negatives and photographic prints of star trails to the collection of the American Museum of Natural History. For these and other activities he became in 1936 a member of the Columbia University Camera Club.

Hanson Wilson was highly respected by his associates in professional life and elsewhere. His reliability and uprightness of character won the esteem of many friends.

Mr. Wilson was elected an Associate Member of the American Society of Civil Engineers on June 30, 1911.

JOHN SOULE BUTLER, JR., Jun. Am. Soc. C. E.[1]

DIED DECEMBER 18, 1940

John Soule Butler, Jr., will be but a name to the many who read these pages; but to those who shared the privileges of intimate friendship with John the name brings to life an unusually gifted young man well founded in sincerity, integrity, and intellect.

---

[1] Memoir prepared by Almon H. Fuller and Frank Kerekes, Members, Am. Soc. C. E.

The son of the late Lt.-Col. John Soule Butler, M. Am. Soc. C. E., and Abbie Holton (Throop) Butler, John was born on March 18, 1914, in Nashville, Tenn. Colonel Butler, a graduate of Vanderbilt University in Nashville, had been with the Corps of Engineers in civilian capacity for twenty-three years when he was commissioned a Major. One of the many outstanding achievements of Colonel Butler was a report upon the Columbia River Basin in the State of Washington, including the possibilities of the Grand Coulee Dam.[3]

As a son of an army engineer, John benefited from travel and broad contacts, as exemplified by his elementary school attendance at the Wilson Dam County School near Florence, Ala.; at the Balboa Grade School, Panama Canal Zone; and at the Reid Grade School, Seattle, Wash. He gave early indication of his brilliance by completing "With Honors" in two and one-half years the regular four-year high school course in Seattle. At Iowa State College, in Ames, where he enrolled in 1931, he soon established himself as an exceptional student who was more interested in high achievement than in grades. Upon graduation in June, 1936, from the Department of Civil Engineering with the degree of Bachelor of Science, his scholastic average placed him at the top of the list of civil engineering graduates. He was elected to the honor societies of Tau Beta Pi and Phi Kappa Phi.

The summer after John's freshman year he worked for the General Land Office on surveys in northern Minnesota. He left college during the junior year to work again with the General Land Office, returning a year later to finish his college course. Immediately following graduation he was employed by the Chicago, Milwaukee and St. Paul Railroad Company but had to relinquish his position in less than a year because of ill health. After two years, when his health had improved sufficiently, he began work for the Building Department of the City of Denver, Colo. In September, 1940, he left Denver to accept an appointment in the National Advisory Committee on Aeronautics in Virginia, where he was at the time of his death.

A real student by nature, he read and studied almost constantly. During the last year of his life he took graduate courses in mathematics, leading toward a Master's Degree, at the University of Colorado in Boulder. Barred by physical disability from participation in all forms of athletics except swimming, his recreational interests lay largely in chess and contract bridge. His college roommate for three years writes:

> "As a man, John was loyal and dependable. He did not have a wide circle of friends, but was a very sincere, close friend of those who knew and understood him. He had the highest respect for those who earned their own way through college. He loved the simple way of living. Whatever he undertook, work or play, he put into it the best that was in him. He played chess and bridge with the champions. He was an excellent swimmer and, although he was not on the team, he acted gratuitously as the tutor for many varsity swimmers who needed this type of coaching more than training in swimming. He was a profound student of mathematics. He had the ability to set up facts which were

---

necessary for the solution of a problem. He accepted no man's word, theory or solution until he had worked out the proof by his own reasoning."

Those who really knew him, whether classmate, faculty, or employer, recognized a keenness of intellect which few possess. The tragedy of an early death has deprived society of the benefits of a very unusual constructive mind. The loss is lessened, however, by the inspiration and the guidance which John had given his associates for more than a decade and by the fact that his influence will be reflected in the lives and the accomplishments of others.

On July 27, 1935, he was married to Mary Evelyn Smith who attended Mundelein College in Chicago, Ill. A daughter, Jill Butler, was born on June 2, 1936. Besides his widow and daughter, John is survived by his mother; by two brothers, Phares Throop Butler and Francis Stringfield Butler; and by a sister, Clyde Butler (Mrs. Stanley DeVore).

Mr. Butler was elected a Junior of the American Society of Civil Engineers on November 9, 1936.

MAURICE LEONARD SHULTZ, Jun. Am. Soc. C. E.[1]

Died April 29, 1941

Maurice Leonard Shultz was born in Atlantic City, N. J., on April 17, 1913, the son of John and Fannie (Sacks) Shultz. He received his primary education in Atlantic City and Pleasantville, N. J., and then followed in the footsteps of his brother Ralph in becoming a civil engineer. He received his degree in Civil Engineering from the Drexel Institute of Technology, Philadelphia, Pa., in June, 1936. While at Drexel he was active in the engineering profession, being employed by the United States Coast and Geodetic Survey. He was also a member of the Reserve Officers Training Corps.

After graduation, Mr. Shultz became a civilian employee of the United States Engineer Department where he devoted most of his time to the engineering technique of flood control. He left the flood control field to engage in the work of rebuilding army camps. Soon after the call to the colors (February 9, 1941) he entered active service as a Second Lieutenant in the regular Army Engineer Corps. After a brief stay at Fort Dix, New Jersey, he was transferred to Fort Buchanan, Puerto Rico, as a First Lieutenant in the Engineer Corps. His duties were particularly concerned with the building of strategic roads and bridges on this vital island. He was in the process of redesigning and reconstructing bridges built 200 years ago by the Spanish, so that they would be wide enough and capable of supporting military loads, when he was stricken with lobar pneumonia. After a short illness Lieutenant Shultz passed away on April 29, 1941. His sudden death came as a tremendous shock to his many friends in the social and business world.

---

[1] Memoir prepared by I. M. Levitt, Asst. Director Fels Planetarium, The Franklin Inst., Philadelphia, Pa., and Edward Semel, Philadelphia, Pa.

The outstanding qualities of Lieutenant Shultz were his character, personality, and fellowship. These features endeared him to all who considered him a friend. His hobby, photography, became his servant in his work; he made extensive photographic surveys of all operations in which he was engaged.

He is survived by his mother, his brother, Capt. Ralph Shultz, and three sisters, Esther (Mrs. L. W. Potler), Dora (Mrs. M. E. Baker), and Tilma.

Lt. Maurice Leonard Shultz's early departure from this earth cut short a promising career, for, with his character, vision, and keen intellect, much was expected of him by those who knew him well.

Lieutenant Shultz was elected a Junior of the American Society of Civil Engineers on December 14, 1936.

HENRY JOHN WENDEROTH, Jun. Am. Soc. C. E.[1]

DIED JULY 2, 1941

Henry John Wenderoth was born at Salem, Ore., on November 19, 1914, the son of Harry J. and Grace (Keizer) Wenderoth.

His schooling was begun in the public schools of Salem, and he attended high school at North Bend, Ore. He entered Oregon State College at Corvallis, Ore., when he was seventeen, and received the degree of Bachelor of Science in June, 1937. In college he was elected to the Sigma Tau National Society. He was also a member of the Alpha Chi Rho social fraternity.

As a graduating student Mr. Wenderoth was awarded the Portland, Ore., Section prize for his paper entitled "Forecasting Rainfall by Mean Seasonal Distribution."[2] The prize was the entrance fee into the Society and dues for the first year.

Mr. Wenderoth's first experience with the Topographic Branch of the U. S. Geological Survey was in 1934 when he worked as a rodman during the summer vacation. He worked also during the next season; then, after his graduation in 1937, he took up the work again, first as recorder and then as instrumentman, until July 1, 1939, when he received his Civil Service appointment as junior topographic engineer. He had mapping or leveling assignments in the states of Oregon, Washington, California, Arizona, and Nevada. He was very much interested in photogrammetry and was engaged in this comparatively new field of engineering at the time of his last illness. His death occurred at Salem on July 2, 1941.

In the brief period allotted to him, Mr. Wenderoth had already demonstrated a standard of industry and performance that left no doubt of his ability to excel in his chosen field of work. He was well liked by his associates and had those outstanding traits of character that are essential to success in any field of endeavor.

---

[1] Memoir prepared by George S. Druhot, Assoc. M. Am. Soc. C. E.

[2] *Civil Enginering*, November, 1937, p. 770.

On March 24, 1939, Mr. Wenderoth was married at Del Monte, Calif., to Bettyrae Ella McGahan, who survives him. He is also survived by his parents and a grandmother, Mrs. Mary Wenderoth.

Mr. Wenderoth was elected a Junior of the American Society of Civil Engineers on November 22, 1937.
